hysiologists. In muscular con- the cell shrinks, and in ciliary action the only other visible form of motion then known to occur in animal tissue, the part concerned moves as a whole, so far as we are able to observe it: in the pigmentary changes the form of the cell one of its constituent materials from place to place among the rest. But drawings made with the camera of a cell in successive stages of concentration of the pigment admitted of only one just interpretation.[5]

These changes in the disposition of the pigment accommodate the tint of the animal to that of surrounding objects. A dark frog placed in a white earthen basin in sunlight soon assumes a dull yellow colour and a pale one is not long in becoming black in a covered earthen jar.

It was very interesting to find that light produces these effects not by direct action upon the skin, but indirectly through the retina and optic nerve. A hood of black cloth, carefully arranged so as to exclude light from the eyes without obstructing respiration, entirely prevented a dark frog from becoming pale in bright sunlight. I was naturally desirous of ascertaining through what efferent channels the nervous impulse that caused concentration of the pigment on exposure to light was conveyed from the brain to the foot. Division of the sciatic nerve had no effect whatever upon the colour of the limb. I then tried cutting through all the structures in the thigh except the bone, the femoral artery and vein, and the sciatic nerve. This also had no influence. But when I added to the latter procedure the section of the sciatic, the animal being then pale, it gradually grew dark below the seat of operation till in no long time it presented from the toes to the wound as great a contrast with the rest of the body as if that part had been covered with a miniature black stocking. Thus the regulation of this function, which is probably closely allied to the action of the cells in nutrition, was not carried on exclusively through special nervous channels, as is the case with the contractions of the voluntary muscles, but one nerve could take the place of others in the duty.[6]

Light was not the only agency that induced pigmentary concentration. It might take place rapidly during struggling of the animal, and I once saw a frog grow pale in its efforts to avoid capture. Here mental emotion perhaps came into play, if we may use such an expression regarding the frog. It seems quite astonishing that nervous action should make the pigment molecules rush thus rapidly to the centre of the cell from its remotest and finest ramifications. Yet a sudden gush of tears or outburst of perspiration, although familiar, is perhaps not less wonderful. Concentration of the pigment took place, as we have seen, under nervous influence and diffusion on its withdrawal. But diffusion was no mere passive phenomenon, such as might follow according to any ordinary arrangement of matter when the agency that caused the grouping of the molecules ceased to operate. The transference of the granules from the body of each cell to its remotest ramifications, and their close packing there, were acts such as a living organism alone could have effected. Pigmentary concentration and diffusion were vital functions of a profound character concerned with the relative distribution of different constituents of the cells. Yet from the very happy circumstance of the conspicuousness of the pigment the results of their activity could be observed with the utmost facility and their behaviour in relation to inflammatory congestion easily studied even under a low magnifying power.

The pigment cells pervade the skin and subcutaneous tissue of which the frog's web consists and are especially numerous about the blood-vessels round which their branches twine abundantly. They must, therefore, be acted on along with the vascular parietes by anything applied to the surface of the membrane. And to state shortly the result of many experiments I found that any agency, physical
which caused the blood-corpuscle to lag
sanguinis in the part on which it operated
pigment cells in that particular area incapable of
their functions. Whatever might be their st

resolution occurred.[7]

Thus the pigment cells afforded ocular d
the truth, to which I was otherwise led by inf
an irritant when producing inflammatory c
strates for the time being the vital energies of
on which it acts. It is to be observed that mere
the nervous apparatus of the irritated area woul
followed by diffusion of the pigment, as
section of the nerves in the thigh, so that the
diffusion as well as concentration shows that
pigmentary functions had been arrested. It wa
a familiar fact that nerves may be temporarily

[5] Max Schulze had not yet described the movements of animal protoplasm; and if he had done so this could have gone but a little way in explaining the phenomena described in the text. The gushing out of homogeneous pseudopodia from the granular body of an amœba may, however, be of an allied nature. I made attempts to see the movement of the pigment granules in cells in which concentration was going on; but their extreme minuteness, together with the excessive rapidity of their apparent motion under the high magnifying power requisite, made them generally elude observation. I fancied I saw an infinite rush of something through the clear space around the already accumulated mass but I could not be sure. On one occasion, however, I saw some individual granules leave the mass and make excursions into the colourless fluid, as I could not doubt it to be.

demonstrated the great fact of nervous control
l circulation, but it was not known what part of
centres exercised the function.

g on the inquiry I first divided the sciatic
ceeding which had been stated on high authority
xation of the arteries of the web. The imme-
f its division was, indeed, some enlargement of
ls, but this very soon passed off. I then resorted
s on the roots of the spinal nerves and on the
nd, not to weary you too much with details, I may say that removal of all the posterior half of the spinal cord, that portion which alone gives off branches for the hind legs, caused the arteries of the web to relax completely and to remain permanently of about the same calibre as the veins. But if any portion that furnished nerves to the posterior extremities, whether a little caudal segment or a small anterior part, was allowed to remain, the arteries, after temporary dilatation, resumed their ordinary and varying dimensions.[10]

It was thus shown that the cerebro-spinal axis is the centre that presides over the contractions of the arteries of the foot, and that the function is exercised by the entire posterior half of the cord; and the temporary effect of section of the sciatic proved that, as is the case with the pigmentary functions, one nerve can take the place of others in the duty. We can thus understand how a flap of skin
ject may have
branches in a

An experiment that greatly pleased Dr. Sharpey would seem to indicate that the vaso-mot

seen to contract to con
first experiment with warm water. The contraction of the vessels caused on that occasion by the application of gentle heat to the web was now explained as a "reflex action" through the spinal cord. Their dilatation under irritation remained to be accounted for. In describing that first experiment I stated that the extreme constriction of the arterioles was followed by relaxation to a larger calibre than they had before the water was applied, suggesting the idea of fatigue after exertion. I have now to add that if the warmth was longer continued the subsequent relaxation was more marked and of longer duration, and if the water was made somewhat hotter the contraction that preceded the dilatation was so transient as to be barely discernible.[11]

We seem to have here an exact parallel to what occurred as the result of the action of heat upon the ciliated epithelium. And the natural view seemed to me to be that the ganglion cells of the cord concerned in the arterial contractions were affected by the nervous impulse conveyed to them by the efferent fibres according to the same law that governed the direct action of heat upon the epithelium cells, increased activity or suspension of function being induced according to the degree of energy of its operation. I incline still to believe that this was a correct interpretation of the phenomena of active congestion.

Inflammatory congestion also may be brought about by nervous agency. This fact being of fundamental importance, and not perhaps universally recognised by pathologists, I may describe briefly two unpublished experiments with regard to it which I did shortly after the time of which I have been speaking. Inflammatory phenomena being of a very languid character in the frog I had resort to a higher animal. One of the experiments was simply passing a silk thread through a fold of skin in a rabbit's back and knotting the ends together. When 48 hours had elapsed, the animal having been killed, I removed the portion of skin concerned and examined its under surface. The thread was covered with a yellow line of lymph, around which there was intense scarlet redness for about a quarter of an inch in every direction, contrasting strongly with the paleness of the healthy structures around. And on microscopical examination I found that this depended (to quote from my notes of the time) "partly upon ecchymoses, but chiefly upon well-marked inflammatory congestion of the minutest vessels of the subcutaneous tissue and the deeper parts of the skin."

The other experiment was performed 20 minutes before the first, upon a part of the same animal which, being more sensitive, was more likely to show the effects of nervous disturbance. By means of a fine sewing needle I passed a delicate thread of silk through the superficial layers of the left cornea and cut the ends off close with scissors. Next day the eye was much inflamed and its condition was aggravated on the day following, while the other eye remained

[11] Brief contraction of the vessels, followed by dilatation, had been previously observed by others as the result of the application of irritants to the frog's web.

healthy. As I have already said, the rabbit was killed on the expiry of 48 hours. This having been done by pithing, I at once divided the blood-vessels in the neck while the heart was still beating so as to allow all blood that was free to flow to escape from the head. I then removed the two eyes and cut them both across transversely midway between the cornea and the optic nerve and compared the inflamed eye with the healthy. I will not detain you with a description of the anterior halves of the globes, though they were very interesting, but will at once speak of their posterior portions, more remote from the part where the exciting cause had been in operation on the left side. In that eye the retina was much more readily detached than in the right and showed small spots of ecchymosis. The two choroids presented a striking contrast, "the vessels in the right eye," to quote my notes again, "being not at all conspicuous, while in the left eye the membrane was scarlet, and this depended not merely upon fulness of the vessels but upon darker tint of their contents in consequence of excess of red corpuscles."

It is matter for discussion how inflammatory congestion is brought about by nervous action. It may be doubted whether active congestion could alone give rise to it, though it is by no means inconceivable that the excessive supply of the nutrient fluid might in time exhaust the tissues by over-stimulation and so bring about more or less of that impairment of vital energy which we have seen reason to regard as the essential cause of the blood-corpuscles lagging behind the liquor sanguinis. Or it may be that the nerves produce this weakening effect upon the tissues by immediate action upon them. From that point of view the proof afforded by the pigment cells of the influence of the nerves over processes going on within cells seemed to me peculiarly interesting. And we can conceive of nervous impulse impairing their energies either by over-stimulation followed by exhaustion or by immediate prostration of their powers as by an electric shock.

That the latter idea is not altogether out of the question seems to follow from a kind of experience familiar to surgeons. I will mention one instance of this which produced a great impression upon me. A healthy man, in the middle period of life, had been operated on by lateral lithotomy. All went perfectly well till about 10 days had elapsed, when the renal secretion, which had passed through the wound since the operation, flowed for the first time through the natural channel. In those days, when lateral lithotomy was the routine treatment of calculus, it was well understood that the mucous membrane becomes in a few days unaccustomed to the urine, which then acts upon it with irritating effect, and the result may be a violent general nervous commotion in the shape of a rigor. This may be immediately followed by complete suppression of secretion by the kidneys, and if this does not pretty soon pass off it is fatal. Such was the case with the patient to whom I am referring. In spite of hot applications to the skin—which sometimes work like a charm in such circumstances, operating, as it would appear, by distracting, so to speak, the attention of the nervous system from the affected organs—that man died within a few hours of the rigor. On post-mortem examination the kidneys presented on section an appearance that I have never forgotten—scarlet redness throughout what in other respects appeared to be perfectly sound structure.

The previous healthiness of the patient seems to preclude the idea that this grave disorder of the kidneys could have existed before the rigor. We are therefore led to believe that the prostration of vital energy which inflammatory congestion implies was caused by the irritation in the urethra. If such was the case the remoteness of the kidneys from the source of disturbance makes it certain that the disorder was brought about through the nervous system. This effect could not possibly be produced, like arterial relaxation, by failure of the nerves to act. For we know that the tissues retain their vital energies for a considerable period after entire severance from the body, as is illustrated by the success of Thiersch's method of skin-grafting. We are therefore driven to the other alternative and conclude that the inflammatory congestion of those kidneys was caused by nervous action upon the renal tissues, and the suddenness with which the effect was produced strongly suggests the view that the prostration of their vital power was the primary effect of an unwonted nervous impulse.

Abnormal effusion of liquor sanguinis from the vessels, another marked feature of acute inflammatory disturbance in man, would seem to be a natural result of inflammatory congestion. I used to illustrate to a simple experiment the enormous increase which in the pressure of a liquid upon the walls of a which it is flowing when an obstacle is op passage. When, therefore, the corpuscles begin capillaries the plasma will naturally be for quantity through their porous walls. When assumes an intense degree the effused liquor the peculiarity of being coagulable, producing b fixation the characteristic "brawny" swelling among which it is poured out. In this respect it the normal plasma forced by pressure through t healthy capillaries as the result of venous obst the swelling has the "doughy" character of œ dition also caused by inflammation of a mild that point I shall have occasion to refer again.

I designated by the title "direct infla morbid state produced by the direct operation agents upon the tissues as distinguished from in brought about through the medium of the ne This distinction appears to me to be of great and it enables us to understand what would ot quite unintelligible. One beautiful instance of behaviour of a recent wound in tissues previou When our means of arresting bleeding were les than they are at present it was no uncommon t summoned a few hours after an operation on hæmorrhage. It was a sad thing to have to te the lips of a wound already well glued together in order to gain access to the bleeding point. was neither more nor less than liquor sanguinis been effused from the cut surfaces and had From the quality of the effusion we should supp had to deal with inflammation of a very intense yet the lips of the wound were perfectly pale a free from the active congestion which is the very e of inflammatory disturbance. How could this in reconciled? Very simply, as I believe, by the aid ciples which we have been discussnig. Mechanical a noxious agency producing effects proportio degree. A very blunt implement passing through kills the surface of the parts which it divides; and days we had to poultice a "contused wound" till t separated. A sharp knife does not destroy any tissues, but it throws them in a microscopically into a state of intense inflammatory congestion, with effusion of coagulable liquor sanguinis. noxious agency is only momentary in its operati no time to cause active congestion through t system, but at once leaves the injured tissues free by virtue of their own inherent powers. If the be very sharp the layer of lymph will be very t some other disturbing cause come into play. always sufficient in amount to serve the beautiful adhesion. It is comparatively rarely that direct tion is met with thus pure and simple in prac two forms, the direct and indirect, are co or less associated. Thus, putrid discharge in is an acrid irritant, as I once experienced in the keen smarting of an abrasion on the back of smeared accidentally with the pus of a stump dressing. Hence during the period that elapses divided tissues are clothed with that wonderful layer which we term granulations such disc direct inflammation in the structures on which it diately, while it also induces in neighbouring parts tion through the nervous system.

When Marion Sims had published his remarka with the silver suture in gynæcology I resolved trial in general surgery. At that time, as assist in the Royal Infirmary of Edinburgh, I had ch Lock Hospital, and one of the patients having matous tumour of the scalp I removed it and b edges of the skin together with a silver stitch. required ligature and the wound healed without As the suture created no disturbance I left it about ten days, when I took the patient over to and showed him the skin about the wire perfectl natural in appearance without a trace of discharg a silk stitch would within four days have infalli suppuration with surrounding redness. Mr. Sym recognised the importance of the facts and from forward the silver suture was used for all more convenient and no longer

gulation of the blood, while it is a matter of l importance in physiology, has peculiar interest unt of the special feature of coagula- exudations and the part played by of wounds, and various other patho- h as the sealing of divided arteries by

Towards the close of the investigations which I lescribing there was published another successful per Prize essay, "Coagulation of the Blood," the subject selected by the judges for the com- The author of this dissertation, the late Dr. , propounded the new theory that the solidifica- ood shed from the vessels was due to the ammonia, which, as he believed, held the lution. I was at first much struck by the lth which he supported this view, and my first s on the subject were made with the object of ng that evidence where it seemed to me weakest. these, a sheep having been placed under chloro- ght by means of a common tourniquet to constrict so extremely as to prevent the ammonia from the vessels were divided and so keep the blood of amputation. Rigidity of the muscles pre- m carrying out my intention, but I tied a mly round the foot below the joint where the noves it, so as to retain the blood and, as far as the ammonia also. The foot being severed, I me, and, having raised a portion of the skin xpose a subcutaneous vein, I investigated the blood in it. I found it indeed fluid, with one full of significance, though I did not see its e time—viz., where the cord used by the butcher e feet together had pinched the veins against the , and there only, was the blood in them coagu- emember being a little disappointed, as well as that appearance. It was not in harmony with n which I was at the time disposed to believe w replete were the facts with possible instruc- pression of the veins had certainly given no for escape of ammonia It is equally certain rd did not make the blood coagulate by any n upon it; for the cord, so long as it remained in pt the parts of the veins which it compressed lood. It is clear that the effect was due to the e cord upon the walls of the vessels. Not that it d them, nor is there any reason to suppose that it hem. No doubt if the animal had been released slaughtered the veins would in due time have But the mechanical violence which the hard exerted, being pretty severe and long continued, ted for the time the vital energies of the tissues t had acted, and we had in coagulation of the etition of the class of phenomena which we had he blood-corpuscles.

was it that the blood remained fluid in other parts ls? To my surprise I found that the same con the case for days afterwards. And thus accident recognise what I afterwards found to be the e—viz., that the blood, though in mammalia it soon after death in the heart and main trunks, l for an indefinite period in minor branches. The the heart had been an object of familiar observa- -mortem examinations in the human subject and have been assumed that the same thing occurred the vascular system.

's foot with the blood retained in its veins by a plied before the animal was slaughtered afforded nity for very simple but instructive experiments lations between the living vessels and For that the veins retained their lapse of more than 24 hours after [illegible] by muscular contraction on exposure.[12] Thus I found that a piece of glass introduced into a vein occasioned coagulation in its vicinity The end of a sewing needle pushed through the wall of a vein otherwise uninjured became after a while encrusted with a layer of fibrin deposited upon the part within the vessel, while the rest of the blood in it retained its fluidity.[13] On the other hand, having injected air into the vessels on another occasion, I found seven hours later that their contents were a frothy mixture of blood and air, the walls of the bubbles of which were fluid but solidified when shed. Sir Astley Cooper had been of opinion that the living vessels kept the blood within them fluid by acting in some way upon it—in other words, his view implied that the blood had a spontaneous tendency to coagulate which was held in check by the active operation of the living tubes that contained it.[14] Facts such as I have just mentioned seemed to me to indicate that the ordinary solid was the active agent, determining the formation of fibrin as a thread does the deposition of sugar candy, while the healthy living tissue had the remarkable peculiarity of being destitute of this general aggregating property of solids, behaving rather like the self-repelling particles of gases.

It was not only in vessels of small size, like those of the sheep's foot, that the blood remained fluid in parts severed from the body. I found that the same was the case in veins of the dimensions of the jugular of the ox or the horse, and this in spite of their entire detachment from surrounding structures. The vessel being exposed after the animal had been felled at the abattoir two ligatures were applied in order to retain the blood in it, after which it was removed and taken home with as little disturbance as possible. The blood in it retained its fluidity for upwards of 24 hours, affording opportunity for most instructive experiments. Of these I must content myself with describing one. A portion of an ox's jugular with its contained blood being held vertically the upper part was removed along with its ligature and the lips of the now open venous compartment were held apart with forceps by aid of an assistant, while a thin glass tube, of rather smaller calibre than the vein and open at both ends, was passed down into the vessel with the utmost steadiness so as to disturb the blood as little as possible. The upper end of the tube had been drawn out with the blowpipe to much smaller size and a short piece of india-rubber tubing adapted, so as to admit of clamping with catch-forceps. When blood appeared at the end of the caoutchouc tube the clamp was applied. The whole apparatus was then rapidly inverted and the piece of vein removed, leaving the blood in a vessel of ordinary solid matter without any contact of living tissue. The glass tube was steadily clamped to a retort stand and its orifice covered with a loose cap of guttapercha tissue to exclude dust, after which all was left undisturbed for 24 hours. On then turning out the blood I found it all fluid except a layer of clot about one-eighth of an inch in thickness which encrusted the interior of the tube, and also a little clot at the surface which might be explained by some drying on account of the imperfect fitting of the cap. The fluid part of the blood soon coagulated. The result of this experiment seemed to me of itself sufficient evidence that the blood requires no action of the living vessels to maintain its fluidity and that the hypothesis of such action was superfluous. At the same time the extreme care required in order to ensure the success of such an experiment indicated the subtilty of the influence of an ordinary solid in bringing about coagulation. A very simple experiment performed in a butcher's establishment on the way from my father's house at Upton to deliver the Croonian Lecture before the Royal Society illustrates the same thing. I received blood from the throat of an ox into two similar open earthen jars (gallipots), and slowly moved a clean glass stirring rod through the blood of one of them for a second or two, and then left both vessels undisturbed. In the course of a few minutes the blood that had been thus gently and briefly stirred was a mass of coagulum, while the unstirred blood was still fluid, except a thin layer of clot encrusting the wall of the jar. In course of time it also coagulated completely. Now we know from the experiment with the ox's jugular that coagulation is propagated with extreme slowness, if at all, from a clot in blood perfectly undisturbed. The earlier coagulation of the main mass of the stirred blood was, therefore, not caused by propagation of the process from a layer upon the surface of the jar, but must have been the result of the brief agency of the glass rod.

---

[13] As regards the ammonia theory, an experiment which proved universally convincing was this foot, I pressed the blood out of d. There it soon coagulated; the very substance, a mere trace of which should have kept it fluid according to the theory in question, having brought about its coagulation ary considerably foot was removed id impairment of and finally loses ter the veins have lost all life

[14] Brücke of Vienna, who had also competed for the Astley Cooper at a similar conclusion. He experimented largely in cold-blooded animals generally. from the body, the blood in its ts fluidity. I had not seen Brücke's ents referred to in the text were performed

A little before the delivery of the lecture referred to,[15] I became aware of the recent very important observations of Schmidt, who showed, as had been foreshadowed many years previously by Andrew Buchanan of Glasgow, that normal liquor sanguinis does not, as had been supposed, contain fibrin in solution, but only one constituent of that substance, the other, which Schwann termed "fibrinogen," being derived from the blood corpuscles. The ordinary solid, therefore, in determining coagulation does not cause the *deposition of fibrin* already formed, but so influences the corpuscles as to make them give up an ingredient necessary for the formation of that insoluble body.[16]

With this further light upon the subject the conclusions derived from the experiments to which I have referred seem to explain the special coagulability of the exudation in intense inflammation. Under intense *irritation the capillary* walls will naturally be affected by the noxious agency as the veins of the sheep's foot were by the constricting cord and, like them, act upon their contained blood as if they were ordinary solids. The plasma of that blood will therefore receive from the blood corpuscles the material requisite for forming fibrin and, passing through the pores of the capillaries with that addition, will constitute a coagulable exudation.[17]

On the other hand, if irritation is less severe, although the tissues are impaired in vital activity, the walls of the capillaries may not be reduced to the condition of acting like ordinary solids in their relation to coagulation, in which case the result will be the effusion of normal uncoagulable liquor sanguinis.

It does not, of course, follow that the absence of adhesiveness of the blood-corpuscles is due to the same cause as the fluidity of the blood. It might quite well be, for example, that the corpuscles are maintained in the healthy condition by nervous action, whereas the state of the healthy living vessel which ensures fluidity of the blood would seem to be a profound property of the constituent matter of the lining membrane which, when in active health, behaves, as we have seen, like a gas rather than an ordinary solid.[18]

In point of fact a very interesting observation which I made long ago, but to which I have not before directed attention in this point of view, proves that an extreme degree of adhesiveness of the red discs may exist within a *blood-vessel the walls* of which are in perfect health with reference to coagulation. If a horse's jugular vein, obtained in the manner which I have described, is suspended vertically, the blood in it remains fluid for an indefinite period, but the red corpuscles soon fall from the upper parts of the fluid, leaving a buffy layer of plasma, readily seen through the translucent wall of the vessel, just as occurs in blood outside the body. And this behaviour of horse's blood implies, as we have seen, a very high degree of adhesiveness of the red discs. If we compare this with the perfe absence of grouping of the red corpuscles which w observed within a vein of the bat's wing in spite of the extreme adhesiveness in the same animal in blood shed fro the body, we cannot but be greatly struck with the contras As regards the circumstances of the two vessels we see th in the bat's wing the vein was a small one in its natur relations to surrounding structures, whereas the horse jugular was of very large dimensions and isolated from t rest of the body.

It seems impossible that the adhesiveness of the corpuscl in the jugular vein was the result of isolation fro other structures; for adhesiveness of corpuscles is n occasioned in the vessels of the frog's web by amputati of the limb, nor does the state of the tissues that causes result from complete detachment from the body in t human subject, as we may safely infer from the persiste healthiness of a piece of skin entirely transplanted in ski grafting. We seem, therefore, forced to the conclusi that what keeps the blood-corpuscles *from adhesiveness* is local function of the tissues, quite distinct from th molecular constitution of their component material whic renders them neutral in relation to coagulation of the blood and it seems necessary to ascribe the adhesiveness of t red discs in the horse's jugular to the mass of the blood i it being too great for that function to control. This fun tion, unlike that property of the tissues which ensur fluidity of the blood, must therefore exert an active influenc upon the vital fluid. It would seem to be *much more* eas disturbed by noxious agencies, for adhesiveness of corpusc may exist in any conceivable degree according to the degr of irritation, whereas coagulation seems to imply severe di order.

The mobility of the black pigment granules of the fr has often struck me as extremely remarkable. Perfe absence of any tendency to aggregate on their part mu be fully as essential to the freedom with which they mov through the exquisitely delicate *ramifications* of their co taining cells when diffusion gives place to concentrati as want of adhesiveness of the blood corpuscles is to th free transit through the capillaries, and I cannot but thi that the two phenomena are analogous. It may be, for an we know to the contrary, that the pigment granules may themselves living entities. Their uniformity in size is favour of such an idea. *Our fathers* would have be greatly astonished to learn that the chlorophyll grains vegetables were, as has been shown in recent years, liv organisms multiplying by division like the nuclei of th containing cells; and though the pigment granules much smaller they are probably greatly surpassed minuteness by many microbes which, though hithe invisible to us, we believe from analogy to be the cau of some infective diseases. But, however this may the perfect mobility of the pigment cells seems me a special property which they possess as constitue of the living body, in other words, to use once mo the expression which in the present state of our knowled is indispensable, a vital property. If this be so, we und stand what would otherwise be very unintelligible—t that when the pigment cells have their functions tempora suspended by a noxious agent the granules do not bec diffused as they do when withdrawn from nervous influe but remain exactly as they were before the irritant applied, whether concentrated, diffused, or in any inte mediate state. If we suppose that the pigment cells, l the blood corpuscles, acquire under irritation a tendency mutual aggregation which they do not possess in health, follows as a matter of course that when vital energy suspended by the noxious agency they will adhere toget and retain for the time their relative positions.

After being appointed to the Chair of Surgery in University of Glasgow I became one of the surgeons the Royal Infirmary of that city. Here I had too am opportunity for studying hospital diseases, of which most fearful was pyæmia. About this time I saw opinion expressed by a high authority in pathology t the pus in a pyæmic vein was probably an accumulation leucocytes. Facts such as those which I mentioned having aroused my interest in my student days in a of pyæmia made such a view to me incredible, and determined to ascertain, if possible, the real state of thi by *experiment.* I introduced into a vein of a li horse a short glass tube open at both ends, cont ing a piece of silver wire in which was mounted of calico, which I thought likely to give y to putrefactive change, shutting off the vein concerned from the general circulation by igature. After the lapse of some days I removed compartment and found that the blood in it had very remarkable changes The limits of this ich have been already too widely extended) make le for me to enter into details, as I had hoped to regarding the researches of which this was the nent. I must content myself with stating the con- which I was led at the time I am speaking of, and confirmed by later investigations—viz., that the n of septic material into a vein may give rise to the opment of large nucleated cells which, growing at [illegible] ients of the coagulum, con- [illegible] liquid. The pus so formed [illegible] hose which I sketched in ase at University College, are not pus corpuscles dinary sense, or leucocytes, but the variously or less granular nuclei of the large cells the dies of which const [illegible] estion of the origi [illegible] t not enter. This [illegible] d clot removed all [illegible] ing the post-mortem appearances in pyæmia and ical features. Having become familiar with the s of these cells in suppurating coagula I was able e them in acute abscesses in the human subject onstrate them to others by mixing carmine with [illegible] render clearly defined the limits of the [illegible] the cells which otherwise would have been [illegible] *puris*.

[15] Vide the Croonian Lecture on the Coagulation of the Blood, Proceedings of the Royal Society 1863

[16] Regarding the corpuscular elements of the blood which are concerned in supplying to the plasma the materials necessary for the formation of the fibrin and the chemical interactions of those substances various important researches have since been conducted in which I have had no share.

[17] I once ascertained the coagulability of a drop of clear fluid which had exuded from a recent contused wound by drawing the point of a needle through it, to which it yielded threads of fibrin.

[18] It has been shown of late by Professor Haycraft that an indifferent liquid, such as liquid paraffin, has a similar negative behaviour in relation to coagulation, so that by proper management blood may be kept fluid in a vessel of ordinary solid matter smeared with that substance.

course, aware of the great importance of the of leucocytes discovered by Cohnheim and mmeasurably more interesting by Metchnikoff's of their phagocytic powers, and I know that of pus have often such an origin. But I am fied that this is not the exclusive mode of pus and that it is often produced by the proliferation was first taught by my illustrious predecessor in of two years ago (Professor Virchow) in the Pathologie."

ese investigations into the nature of pyæmia eding I was doing my utmost against that deadly Professor Polli of Milan having recommended the ministration of sulphite of potash on account of trescent properties I gave that drug a very full prophylactic. I have notes of a case in 1864 ter amputating the thigh for disease of the knee- e ten grains of the sulphite every two hours from f the amputation; and when on the sixth day an gor occurred, I doubled the frequency of the admini- Death, however, took place nevertheless, and this means my only experience of such disappointment e time I did my best by local measures to diminish f communicating contagion from one wound to freely employed antiseptic washes, and I had on the y wards piles of clean towels to be used for drying nd those of my assistants after washing them, as should invariably be done in passing from one another. But all my efforts proved abortive; as ardly wonder when I believed, with chemists that putrefaction was caused by the oxygen of will thus be seen that I was prepared to welcome lemonstration that putrefaction, like other true ons, is caused by microbes growing in the substance Thus was presented a new problem: lude oxygen from wounds, which was impossible, ect them from the living causes of decomposition by h should act with as little disturbance of the tissues tent with the attainment of this essential object n since shown that putrefaction, though a most se of mischief in wounds, is not its only cause ords, it has been proved that there are microbes duce poisons that do not occasion unpleasant t the principle that first guided me still retains, I full value, and the endeavour to apply that o as to ensure the greatest safety with the least disadvantage has been my chief life-work.

HOMAS'S HOSPITAL MEDICAL SCHOOL.—nce Scholarship in Natural Science (£150) was Mr George Young Worrall; and the University p in Anatomy and Physiology (£50) was awarded lter L Harnett, B A.Cantab.

An Introductory Address
ON
SCIENCE AND PRACTICE.

Delivered at the Opening of the Winter Session at University College, London, on Oct. 1st, 1900,

BY GEORGE VIVIAN POORE, M.D.,
F.R.C.P. LOND.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE.

GENTLEMEN,—It is 19 years since I last had the honour of delivering the introductory address to the students of the Faculty of Medicine in this college. Since October, 1881, inevitable changes have taken place. Many of those who were then our chiefs are now no more; others have retired from the labours of professorial work; their places have been supplied, let us hope, by good men and true, all of them anxious to maintain the high traditions of this college. In 1881 some of my colleagues were beginning to talk of reconstituting the University of London. That reconstitution has now taken place. The headquarters of the university have been removed from the City of Westminster to the newly-incorporated town of Kensington, and all the medical schools in London have become constituent colleges thereof. Since 1881 the Universities of Oxford, Cambridge, and Durham, as well as the Victoria University at Manchester, have made, and are making, ever-increasing efforts to meet the needs of the medical student. In connexion with the new University of Wales a medical school has been founded in the flourishing town of Cardiff, and the present year has witnessed the foundation of the University of Birmingham, which, under the guidance of the Right Honourable Joseph Chamberlain and Professor Oliver Lodge, both of them former students of this college, may reasonably be expected to attain a large measure of success. I believe that competition is the very essence of progress and that the largely increased competition in the matter of medical education is full of good omen for the future of medicine in this country. So long as the competitions be really free there is nothing to fear. So long as men be really free to back their own judgment in the matter of gifts and endowments, and so long as the medical student be free to choose the schools and the teachers to which he will take his educational fees, there can be no doubt that the law of the survival of the fittest will continue to exert its beneficent influence and that progress will result.

I purpose to-day to address myself to those of you who are about to commence the study of medicine proper Your studies hitherto in chemistry, anatomy, and physiology, studies which are a necessary preliminary to the study of medicine, have been pursued by the aid of dead material and by methods which are largely artificial—methods many of which have no counterpart as far as we can tell in Nature. You have learnt to recognise and to name the various parts of the human body and to understand the relation which the various organs hold to each other. You have learnt how the chemist, by methods of his own, tears organic matter into fragments and designates the bits by dodekasyllables, and represents them by mystic formulæ which sometimes perhaps illustrate his own imaginings and show his descent from the astrologer and the alchymist. You have learnt by methods which are largely artificial to recognise many of the cellular elements which go to the building of our complex bodies and by means of anæsthetics and sundry artifices you have had an occasional glimpse of vital movements—a momentary and imperfect glance of the fringe of Nature's robe. Your time hitherto has been largely spent in a valley of dry bones and in the laboratory of a crematorium, and many of you who to-day begin the study of medicine are doubtless asking, "Shall these dry bones live?"

The passing from the study of the dead to the study of the living constitutes the greatest epoch in the life of a medical student, and you will readily believe me when I say that the study of the living demands infinite patience and great humbleness of mind. I have alluded to the fact that the methods of the laboratory are largely artificial. We are in necessary doubt as to the resemblance between Nature's methods and man's methods, and how far he who works in a laboratory merits the name of artificialist rather than that of naturalist. It is necessary to say this because we have to follow Nature. We must not mistake our methods for her methods. We physicians have to find out what is man's true relation to his surroundings in this world. We are powerless to alter the course of Nature, but we may, perhaps, persuade our fellow men to reform their conduct. Before, however, we begin to persuade, still more before we venture to compel, we must be sure of our ground. We must constantly check the advances of the laboratories by the observations of the broad facts of Nature. Science in its narrow sense must go hand in hand with practice, each must be respectful to the other, like symbiotic organisms living together for mutual benefit. A very dangerous person in this world is the quasi-monocular Polypheme who holds one eye over an immersion lens and keeps the other shut. He becomes doubly dangerous if he be the holder of a public position, which may give to his utterances a fictitious value sufficient, perhaps, to tempt the politician to earn a bubble reputation by hasty legislation, than which there is no more effectual bar to scientific progress.'

"Man, proud man,
Drest in a little brief authority,
Most ignorant of what he's most assured,
* * * * *
Plays such fantastic tricks before high Heaven
As make the angels weep."

Those of you who are passing from the laboratories to the hospital are equipped for your work in a manner which enables you to observe with completeness and to record with accuracy. You may be disappointed in finding that no inconsiderable part of the knowledge which you have hitherto acquired is of little practical use to you in the wards, or at least you may fail to see the bearing which it has upon the treatment of the sick. Be not dismayed; the correlation of knowledge is infinite. We cannot tell from hour to hour what may prove to be the practical bearings of the most recondite discoveries of the laboratory. The so-called practical man who is ever asking the question "*Cui bono?*" is certainly not the one by whom advances in knowledge are likely to be made. If you find that the recording of cases in the hospital has to be done by clerks and dressers instead of by clockwork and drums driven by an electric motor, do not for this or similar reasons rush to the conclusion that you have left really scientific work behind you. It is true that scientific work cannot be done as rapidly in a hospital as in a laboratory and that in a hospital you cannot control the circumstances and conditions of your work as you can in a laboratory. The collection of facts often extends over years and those who are in a hurry to make a so-called scientific reputation should remain in their laboratories. The power of independent observation is a gift which is given to few. The true naturalist—such as Harvey, "Parson" Hales, John Hunter, Gilbert White, Charles Darwin, and Pasteur—would seem, like the poet, to be born and not made, and generally educates himself by methods of his own. We may reasonably hope, however, that the extension of scientific teaching is calculated to bring the unconscious genius within sight of the mental pabulum for which he has, unknown to himself, an inborn appetite.

May I venture to allude to some of the work which has been accomplished by the patient observation of physicians? First amongst these is the solution by Harvey of the difficult problem of the circulation. This was the result of many years of incessant labour and the observation of every fact which by any possibility could assist him. He is credited with having begun to teach the doctrine at least 12 years before he published it in its final form. He was in no hurry, he had no petty ambitions with regard to priority, and finally he left the question completely settled, so that in the 272 years which have since elapsed physiologists have been able neither to add to nor detract from the doctrine that remains pretty much as Harvey left it.

Again, the discovery of the cause of the endemial colic of Devonshire by Sir George Baker deserves ungrudging recognition. Baker's essay was published in 1767 and it is very interesting to contrast his admirably arranged and thoroughly scientific discourse with the essays on the same subject which had preceded it. I need not follow Sir George Baker in his collection of facts and his close reasoning upon the facts collected. Having shown that in all human probability the cause of the colic was to be found in the lead fittings of the cider presses, he finally had recourse to Dr. Saunders, "an ingenious gentleman who practised chymistry" and who extracted a tangible quantity of lead from a dozen bottles of Devonshire cider. No better instance can be found of the happy association of the laboratory worker and the clinical physician. I may, perhaps, remind you that Baker's discovery, although limited to a disease which was peculiar to certain districts only of this country, was in reality very far-reaching, for there were endemial colics in many other parts of the world, such as the colic of Poitou and the "dry belly-ache" of the West Indies and Central America, all of which were ultimately traced to lead as a cause. Lead colic was, prior to Baker's discovery, a very widespread malady and is now happily very rare.

Scientific in its best sense was the discovery made by Ballard, then medical officer of health of Islington, that certain pestilences—enteric fever, scarlet fever, and diphtheria, which hitherto were supposed to "stalk in darkness"—walked occasionally with the milkman. This great discovery, following on that made by Snow and Budd that cholera and enteric fever could be conveyed by water, encouraged the pathologist to renewed efforts, and it was not long before the "ingenious gentlemen who practise bacteriology" were able to demonstrate to the clinicians that the true causes of some of these diseases were recognisable by the eye and that their habits were such as to fit them peculiarly for transit by water and by fluids mixed with water. The great increase of knowledge which has taken place with regard to infective disease in the last half of this expiring century has been due to the coöperation of the laboratory worker and the clinician. Let us give to Pasteur and Koch their due mead of praise, but do not let us forget the credit which is due to Ballard, Snow, and Lister.

The spread of infective disease is, in the opinion of some of our more enthusiastic and less experienced laboratory workers, to be accounted for solely by the existence of a microbe, and having discovered the microbe they are anxious to push the fact to what they are pleased to call its logical conclusion. In relation to the bacillus tuberculosis we hear propositions for killing 80 per cent. of our cows, for making expectoration a misdemeanour punishable by fine at so much per nummulus, for declaring it felony to drink raw milk, and for converting a dairyman into a sort of ticket-of-leave man. No room is to be left for the exercise of private judgment, albeit that clinicians are feeling that the cause of the spread of infective diseases is still enveloped in mystery and that notwithstanding the light which recent discoveries have given us the unknown is certainly greater than the known. The wise laboratory worker will always be chary of moving without the support of the clinician. One great mistake has already been made in Germany in relation to tuberculosis. This should serve as a warning. As a nation we have a reputation for level-headed common sense, and I feel sure that if in these matters we "legislate in haste" we shall "repent at leisure."

The labours of Edward Jenner in relation to the establishment of vaccination were scientific in the best sense. It is only recently that other facts which seem to bear some analogy to vaccination have received attention at the hands of Pasteur, Haffkine, Wright, Fraser, and others, and we have learnt much, but have much more to learn as to the causes of immunity Practice in this matter has been ahead of theory. The scientific use of theories and the discovery of far-reaching principles gives an impetus to practice and endows it with a degree of certainty and security which it could not possess without it.

Many an antiseptic process has been practised in our kitchens from time immemorial. The careful housewife who long since successfully preserved fruit by bottling was anticipating Pasteur Pasteur has shown us the principles which underlie the process, and has therefore given such an impetus to the art of food preservation that we seem almost to be in danger of famine in relation to food which is really fresh. This is a most important matter, for the practical man is beginning to feel that stale food is no true substitute for fresh food, all chemical analysis to the contrary notwithstanding.

The frequency with which practice has anticipated theory and a knowledge of principles is most interesting. The "unbusied shepherd stretched beneath the hawthorn" munching bread and cheese and a raw onion is doing that which his ancestors learnt centuries ago by the light of Nature and the craving of a natural appetite The physiological chemist arrives somewhat late upon the scene to tell him that he has selected for his meal a perfectly correct mixture of proteids, fats, carbohydrates, antiscorbutics, and antiseptics and Corin stares as M Jourdain stared on learning that his conversation consisted of prose If, however, the physiologist were to suggest a change of diet in favour of a more portable assortment of dried proteid, starch, oleomargarine, and allyl compounds, the best products of his laboratory, he would probably attribute the yokel's refusal to impenetrable stupidity. The physiologist unfortunately can tell the shepherd nothing concerning those natural appetites which are the mainsprings of every human action.

In Stanley's "Darkest Africa" I find a very interesting example of practice ahead of theory. In the second volume the author has some valuable observations on malaria, among which I find the following: "Emin Pasha informed me that he always took a mosquito curtain with him as he believed it was an excellent protection against miasmatic exhalations." Emin's practice was right (a practice, I am told, not unknown in India) albeit that he seemed to have no knowledge that the "miasmatic exhalation" against which he was protected was nothing more or less than a mosquito. It is needless to point out how recent discoveries have supported Emin's practice.[1] We must not lightly abandon established practices at the bidding of each unfledged theory. Theory and practice must go hand in hand, each working for the correction and support of the other if the art of medicine is really to progress and the profession to retain its legitimate hold upon the public.

THE NEW HOSPITAL.

The council of this college soon learnt that a medical school without a hospital was not complete, and that for the education of the medical practitioner science and practice must go hand in hand. The old hospital, so soon to disappear, was opened in 1833, and in it an illustrious line of physicians and surgeons have done work which has redounded to the credit of the institution and have sent out students whose subsequent careers have shown how well they were taught and how diligently they worked It is now 20 years since the old hospital was condemned as unfitted for its purposes[1] by Dr. de Chaumont, the worthy successor of Parkes in the Chair of Hygiene at Netley. Sir Francis Goldsmid came forward and made a noble offer to help us to rebuild it—an offer which the council, after due deliberation, refused, notwithstanding that the general committee and the then staff of the hospital were unanimous that rebuilding was necessary. Thus it has come about that we as a medical school have been handicapped in these days of keen competition by being obliged to carry on the most important part of our teaching in a hospital which, when compared with recent hospitals, was obsolete and squalid. Possibly our ill-fortune has been a blessing in disguise, because the construction of the much-needed new hospital has now been undertaken in a spirit of unbounded generosity and philanthropy by Sir Blundell Maple, whose name will deservedly be honoured as that of Thomas Guy is honoured, and whose noble hospital, the form of which is due to the genius of Alfred Waterhouse, bids fair to be one of the chief ornaments of the new borough of St Pancras. As we are about to take possession of the central (administrative) block and one of the wings of the new hospital it will not be out of place if I say a few words about it

The new hospital has about double the area of the old hospital and occupies the entire "island" bounded by University-street, Huntly-street, Grafton-street, and Gower-street Not only is it surrounded by streets but it faces the college green, and considering that it is necessarily placed near the centre of a densely crowded city it may be said to occupy a site which is exceptionally good in relation to light and air. Nearly the whole of the area will be covered by a noble basement 15 feet in height, rising six feet above the pavement and lighted by large windows and skylights. In this basement will be placed the out-patient departments, baths, offices, store-rooms, &c The ventilation of this basement has received special attention and it will be completely cut off from the central and subsidiary staircases and lift shafts which communicate with the superstructure. The wards have an amount of floor space per bed greater, I believe, than is to be found in any other hospital This is most important as conducing to purity of atmosphere and enabling the individual patient to be easily screened off when necessary—a necessity which for one reason or another is of frequent occurrence In a teaching hospital like ours large floor space is required for the accommodation of students. The wards are amply lighted by windows on both sides and it is one of the advantages of the cruciform ground plan which Mr. Waterhouse has adopted that the majority of the ward windows command a view which is singularly unobstructed because there are no buildings which are opposite and parallel to them. The new operating theatres are highly finished and are arranged and fitted after the best models to be found either in this country or the continent. In them, as in the rest of the hospital, light and cleanliness have ever been in the mind of the donor, the architect, and the medical staff, whose opinions at all times have received the most careful consideration at the hands of the hospital committee and the building committee

We have not been unmindful that science and practice must go hand in hand. If medicine is to advance morbid products must be minutely studied by all the methods which are available A novel feature of the new hospital is the range of rooms on the top floor devoted to the chemical, microscopical, and bacteriological study of morbid products and secretions These investigations often give a certainty to diagnosis which a few years ago was hardly dreamt of, and it must be remembered that upon accuracy of diagnosis depends to a large extent the efficacy of treatment. It may, I think, be confidently said that in no hospital will the latest advances of pure science be more promptly available for the relief of the suffering poor than in the palatial establishment which Sir Blundell Maple is building for us. We are entering at once into possession of three new wards containing 72 beds, new administrative offices, new baths, new operating theatres, and new scientific workrooms for the purposes of research and diagnosis The nurses' wing is rapidly approaching completion and when this is finished we confidently expect that the accommodation provided for our resident medical staff, for our matron, and for nurses and servants, will compare favourably with that of any other hospital It need hardly be said how essential it is that young men and women engaged in the arduous duties of attendance on the sick should be housed in the most wholesome manner possible. There can be no doubt that the present and future students of University College will enjoy facilities for the practical study of disease such as were undreamt-of a few generations back.

LECTURING.

The medical student differs from other students in this, that his course of study is largely controlled by the General Medical Council and the corporations. Seeing that mere examination is a very fallible test of knowledge, and seeing that the public naturally want some guarantee of adequate education from those to whom they entrust their lives, the medical student is compelled to produce proof that he has at least dwelt for a season beside those springs of knowledge from which he may have sipped occasionally when so inclined. He is *compelled*, for example, to produce evidence that he has attended certain lectures, and you will only think it natural for me to make some special allusion to the course of lectures on the *Principles and Practice of Medicine* which (*inter alia*) he is bound to attend. Formerly he was compelled to attend two courses of such lectures; now the examining boards are contented with one course.[1] The medical student is still a very much lectured individual. He has very little time to pick up crumbs of knowledge for himself, but his intellectual pabulum is administered at very frequent intervals, often without regard to his appetite or his powers of assimilation

There is an idea that mere lecturing is of little use, that practical work in the laboratory is the only true complement of practical work in the wards, and that the printing press has rendered lecturing unnecessary. There is a measure of truth in this, and therefore it is almost incumbent upon me to offer some apology for venturing to stand before you as a professor whose duty it is to give lectures on medicine not at the bedside only but in a class room. Perhaps I have been tempted to take upon me the duties of professor of medicine by the recollection of my student days and by the consciousness that in listening to the systematic lectures on medicine of my day I spent time more profitably than I have ever done before or since and obtained a knowledge of medicine which I found in no text-book. In listening to those lectures one's enthusiasm was roused, and one went from the lecture-room to the ward with intenser interest and with greater knowledge of how to observe and what to look for. Not many students even of this college had the good fortune to attend the systematic lectures on medicine by William Jenner, because his tenure of the chair extended only to four or five sessions. Sir William Jenner was the greatest lecturer I have ever heard. He appeared to me to have more insight at the bedside than any other physician I have ever met, and assuredly he was the strongest personality with whom I have ever had dealings in this world. As to Jenner's lectures I have never heard but one opinion. That is interesting, because a lecturer, even a good one, is not always in sympathy with all the members of his audience, and you will find that among students there are widely different opinions as to the merits of their teachers Jenner taught from the fulness of his personal knowledge and largely used the vivid impressions made upon him by cases which he had seen for illuminating and illustrating the principles of medicine. When he suddenly interrupted the thread of his discourse with the words, "I saw a case last week which illustrates this," there followed an interesting recital which was vivid beyond belief and left itself ineradicably fixed on the tablets of the memory. Jenner never talked about things which he did not understand; he was a physician in whom there was little of the metaphysician. He knew that intricate arguments on doubtful points, arguments often difficult to follow even by the best of his audience, were out of place in the lecture-room. There was no attempt at oratory, no wasting of the students' time with flowers of rhetoric, no pretentious display of learning, no pedantry, no "side." His style was that of an honest man, brimful of learning, spurred by enthusiasm for his subject, and genuinely anxious to impart knowledge His manner was his own, at once simple and emphatic. He was a man of transcendent gifts and willingly gave of his best even to the least intelligent. Sharpey, who lectured on physiology, was also an expounder of no common merit who devoted much of his time to lecturing and whose lectures, like those of Jenner, were a recurring pleasure The lectures of Ellis, the professor of anatomy, were highly esteemed by many. To me they proved too soothing even at 9 A.M. He fed us, as it were, on a flavourless gruel of uniform quality which, though theoretically nutritious, proved unappetising to some of us. Two, among the other courses of lectures which I attended, were thoroughly bad, mere incoherent and incomprehensible drivel. I have used the word "attended," but I will ask you to interpret this word in a "schedule" sense.

It is not always the man with the most knowledge and the greatest intellect who makes the best lecturer. Some of our greatest men have had very little power of exposition. A notable instance of this was Professor Thomas Graham of this college who became Master of the Mint. He was the greatest chemist of his age and the worst lecturer conceivable Such a man—and I take him as a type—is far better employed in research than in lecturing. The laboratory, not the theatre, is his proper sphere of action.

Lecturing is not reading. The man who keeps his nose on a manuscript while his audience take a nap might well be replaced by a phonograph with a text-book in its magazine. The functions of a lecturer are different from those of a text-book. The lecturer has power of selecting his material and he must be able to keep in touch with his audience. He knows at once when his audience are interested and when they are bored. A lecturer who fails to maintain order in his class has probably mistaken his vocation The student who pays no attention and who comes to lectures on compulsion is an unmitigated nuisance.

I should not have assumed the duties of the chair of medicine unless I were buoyed by the hope of being useful to those of you who are commencing the study of medicine proper and who, while attending my course, will be mainly occupied in filling the junior clinical appointments In a former address I took occasion to remark that man, who to our unaided vision appears to be at most some six feet by two, is, when viewed by the higher powers of the microscope, about as tall as Mont Blanc and two miles wide across the shoulders. Medical studies have necessarily enlarged with the virtual enlargement of the subject of them, and so it has come about that specialism in medicine is very highly developed—perhaps morbidly hypertrophied. This is inevitable; but a student must generalise before he specialises. As an examiner in medicine of some experience I have noted that students often have a most imperfect grasp of elementary principles

Just as it is the business of the professor of anatomy to deal with the entire framework of the body, so it is, I conceive, the duty of the professor of medicine to endeavour to give the student a comprehensive glance of the entire field. If the young student be too early given over to the teaching of specialists his knowledge is apt to be scrappy and he obtains an acquaintance with medicine which may be compared to that which we may suppose the aphis has of the rosebush on which it feeds. The young student needs instruction as to the proportionate importance of different subjects. He needs to know the common things, and his tendency to run after medical rarities to the neglect of more important matters must be checked rather than encouraged.

Some of the modern text-books written by specialists are often misleading to the student, because diseases which are so rare that an ordinary practitioner may never encounter a single case are treated at inordinate length. I was lately dipping into a work in which the diseases of the skin were dealt with by no fewer than 15 different authors. The knowledge, the half-knowledge, and the no-knowledge of these gentlemen had been elegantly rendered in the dermese language and set before the reader, but the word "itch" did not appear in the index. The child playing with a Noah's ark naively remarked that the beetle was as broad in the back as the elephant and the same criticism may be made on some of our modern treatises, which are apt to mislead a beginner as to the relative importance of different diseases.

I trust that it may be my privilege to be of some use to the beginners of medicine and with the aid of the vast amount of material which is ready to our hand in the museum and the hospital to give a solid foundation and scaffolding upon which you may securely build hereafter, as your knowledge and experience increase.

ENDOWED LECTURES.

One of the results of the reconstitution of the University of London may be a diminution in the number of lecturers and an increase in the size of the classes. Thus it will be possible for a man to give some of his best energies to teaching without suffering from comparative starvation. At present few lecturers earn a "living wage." It must be remembered, however, that lecturing is very hard work. Speaking with no little experience I should say that to really hold the attention of an audience for an hour makes very great demands upon one's store of energy. A man who teaches successfully and lectures day after day may well be excused if his output of what is called original work is not very great. Professor Sharpey was one of the most learned physiologists of his time and yet his fame in the field of discovery is small, and one reason for this is, I believe, due to the fact that his best energies were given to teaching. Not only did he lecture six days a week to large audiences in this college but his advice was sought far and wide, and when sought was freely given to all workers in the vast field of physiology.

We hear a great deal about the endowment of research, and if such endowments should relieve original workers from the drudgery of lecturing, for which possibly they have no great love or aptitude, there can be no doubt that such endowments would advance knowledge and prove a benefit to the student in many ways. The endowment of lectureships, especially of lectureships which students are compelled to attend, is of very doubtful advantage to the student. Dr. Johnson attributed the failure of Gresham College to the fact that the lectureships were endowed while the students paid no fees. Such an arrangement was not calculated to bring out the energies of the professor, and if by chance a professor without the necessary aptitude were appointed to a chair failure and boredom were the results. Every professor needs the stimulus of competition and his emoluments ought mainly to depend upon the fees which are freely paid by students who feel that he can be useful to them. In very few cases ought the endowments of a chair to exceed the amount of fees contributed by students. The best form of endowment would be a provision for old age, which should bear some relation not only to length of service but also to the average earnings in the five years preceding retirement. Thus an inducement would be given to professors whose powers are failing to make room for younger men. Doubtless many of you have heard the story of Gil Blas and the Archbishop of Grenada. It seems *apropos*. Gil Blas, who occupied the post of secretary to the archbishop, was one day thus addressed by the prelate: "My chief pleasure consists in preaching. ...... The honour of being reckoned a perf rator has charmed my imagination ...... but I would avoid he fault of good authors who write too long. ...... Wherefore, ny good Gil Blas, whenever thou shalt perceive my pen smack f old age and my genius flag don't fail to advertise me of t." A few months later the archbishop had an attack of poplexy, from which he recovered sufficiently to enable him o mount again his pulpit steps, but the fire of his genius was xtinct and his congregation said to one another, "This sermon smells strong of the apoplexy." Gil Blas, faithful to his duty, [illegible] his grace, but soon found tha[illegible] an incensed author who had [illegible] elf praised. "Go," [illegible] thrust Gil Blas from his closet; [illegible]; I wish you all manner of [illegible] taste." If lecturers and professors are mainly dependent on their earnings there will be *no need of any Gil Blas to run the risk* of tendering unpalatable advice. On the other hand, the man who has successfully given his best energies to teaching ought to be under no apprehension as to his sustenance in his declining years. Open competition with a fair field is the surest protection against discourses which smell of apoplexy, a protection to which students who are compelled to attend lectures have an undoubted right.

An Introductory Address

ON

THE FUTURE OF THE MEDICAL STUDENT.

Delivered at the Opening of the Winter Session at St. Mary's Hospital on Oct. 1st, 1900,

BY H. STANSFIELD COLLIER, F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS, ST. MARY'S HOSPITAL; ASSISTANT SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

LADIES AND GENTLEMEN,—My colleagues have committed to my care the function of bidding welcome to old and new students at the beginning of this winter's work. We are glad to see you, we look forward to a closer acquaintance with you, since a good deal of the brightness of our lives is reflected from the cheerfulness and enthusiasm of your youth; and you are necessary to us, for without you the work of the great charity which we serve could not possibly be satisfactorily done A short time ago I was in conversation with a gentleman from another country who had been diligently reading a new and unpleasant romance of war from the pen of a great authority on the subject of horse breeding. Dealing with this romance the gentleman said so many things that seemed to be true, so many things more than seemed to be true, and so many things that were less than honest, that he made me visibly uncomfortable, and, being polite, he continued: "And yet your Government appears to manage the teaching hospitals of your metropolis tolerably well" I explained to him that the hospitals were maintained by the bounty of the charitable and were under no immediate supervision of the Government. "Is it possible!" he said. "But is there no State department to look after the maintenance of your medical schools?" "None," I said. "But pardon me," he asked, "permit me to inquire, your salaries, by whom are they paid?" "By the students," I said; "but we are not entirely dependent upon school fees, we practise our profession outside." "For you, yes; but does not the State pay your science teachers?" "No," I said; "the students pay" "Ah," he ejaculated, "how rich your students must be." To be quite frank with you, here is shown another reason that we welcome you.

The fact that medical education in this kingdom is independent of State aid is one of the bulwarks of the dignity of the profession of medicine. The primary purpose of our hospitals is the relief of the sufferings of the poor. The necessary conditions and facilities for medical education are a by-product in the process of transforming the bounty of the charitable into comfort, hope, and health for the unhappy, and this by-product uses up not one grain of the raw metal and adds greatly to the amount of the output [illegible] Samuel Lane and the other founders of this hospital, [illegible]ose who have since added to it and those who have for so long striven to build a new wing, have had compassion, not only upon the sick child and injured man of Paddington, but upon humanity everywhere, for the good which you by the knowledge acquired here will be able to do for men will be spread widely, even as far as the most distant battle-field and plague-stricken city.

An old custom has placed you at my mercy for the next 30 minutes or so in order that the cup of counsel may be offered to you and that a trial may be made of your patience—a quality necessary for your success. For your encouragement I may tell you that you are happier than your fathers were in that this is the only written discourse to which you [illegible] you that your teachers are [illegible] y first advice to the new- [illegible] to the good counsel which [illegible] few days from your parents and friends. There was more to strengthen you for the battle of life in that last hand-grasp of your father than you will find in all the addresses you will ever listen to. No words will help you as much as those which your mother breathed when you parted from her. Keep them ever in remembrance. Each of you has conceived a picture of his future as a student of medicine in bright or sober colours, according to his temperament, probably cheerful, simple, and perhaps with little meaning in it; but as the future becomes the present the visionary picture fades, and in its place is a real and totally different picture, beautiful or ugly, as you shall paint it, but always of great significance and never without light and shadow. Do not work only when the sun shines. Let no discouraging circumstance make you relax your efforts. Remember that some of the best work ever done has appeared for the time to be unfruitful, and that no one can always appreciate his progress. Real work never yet was a continuous pleasure, enthusiasm must ebb and a sense of duty take its place.

Your energies must at first be *devoted* entirely to the acquisition and storing of facts; see that they be well arranged and tidily stored. The best student is not necessarily the man who learns most easily, but he who has made it his habit to keep in order the storehouse of his knowledge that the grain of his harvesting be kept from decay. Of course, memory is made up of [illegible] in an equal degree by everyo[illegible] that effort and the habit of re[illegible] out which the best natural gifts are worthless, and by means of which the least favoured may attain to high proficiency in the art of remembering. But you will not long remain mere collectors of facts; you will soon be able to use them with understanding in the process of thinking for yourselves—an exercise pleasurable even in the smallest matters. May I read to you some quaint words of John Locke? "He that hawks at larks and sparrows has no less sport, though [illegible] soul so it is employed with a greater and more constant delight than any other. Its searches after truth are a sort of hawking and hunting wherein the very pursuit makes a great part of the pleasure Every step which the mind takes in its progress towards knowledge makes some discovery which is not only new, but the best too, for the time at least. For the understanding, like the eye, judging of objects only by its own sight, cannot but be pleased with what it discovers, having less regret for what has escaped it because it is unknown. Thus he who has raised himself above the alms basket, and not content to live lazily on scraps of begged opinion sets his own thoughts on work to find and follow truth, will (whatever he lights on) not miss the hunter's satisfaction. Every moment of his pursuit will reward his pains with some delight, and he will have reason to think his time not ill spent even when he cannot much boast of any great acquisition." In these words does not Locke discover an excellent spirit in which *to strive and to* meet in the right way the checks, blank drawings, throwings out and fallings off which are incidental to all work? As your ideas become more complex, and leaving the more sure ground of knowledge you travel towards the unknown, imagination comes to *you*, to be a help or danger as you use it well or ill—a help if firmly linked with what is known, a snare if uncontrolled.

Two words are often abused by students when they are speaking of one another. They are the words "practical" and "theoretical." "So and so is a practical man and So-and-so is theoretical" The former is used as a term of commendation, the latter in a disparaging sense. These terms must be thoroughly understood or they are dangerous to the young student. In its proper sense, as applied to a student, the word "practical" signifies that he has the faculty of applying knowledge to useful ends and therefore necessitates *the premiss that he possesses knowledge* But this word is so often misapplied that the beginner might almost be led to think it is a virtue to shun books and lectures, to turn out to grass his mind, and with a carpenter-like industry to busy only his neuro-muscular system in the more mechanical parts of work. When the word "theoretical" is properly made a term of contempt it is used in a debased sense, having no connexion with theory and signifying simply "not practical." I have not found that the mind of the unpractical man is overburdened with theory or with anything else save dreams and aspirations. The word "theory" in any of its dictionary meanings commands respect—whether it is used in the sense of "an explanation or system of anything" or "an exposition of the principles of a science or art," or as a hypothesis not yet proved or disproved by facts. Using the word in the last sense it is true that a theory is *sometimes only a will-o'-the wisp*, but at times it is the dawn of a bright new day of knowledge. And here is an instance especially pleasant to all of us. Until very recently the essential cause of rheumatic fever was unknown. It was conjectured to be a micro organism, but this was not proved, and for the time it was necessary to be content with the germ-theory of this disease. It has been the well-deserved good fortune of two St. Mary's Hospital men, who not very long ago were in your position, to give this theory substance, and their work will, I doubt not, in the coming time pave the way to the overthrow of that monster which has made desolate so many hearths, which has done to death so many of our loved ones.

Let me commend to the beginner the practical study of anatomy. It is in the knowledge of this subject that now and then a modern student compares unfavourably with his predecessors. The reason is not far to be sought. The studies of modern physiology and biology are so fascinating that the student's interest does not relax until the daylight fades and tired nature demands rest and tea. He learns a great deal about anatomy—all those things which can be taught him by the clever word-pictures of teachers and books—he passes anatomical examinations creditably enough, though the impressions on his mind are not vivid and lasting, but one might almost wish that the lecturer and demonstrators were less cunning in the art of teaching, for he relies more upon their words than upon his own handiwork in the dissecting-room; he cultivates the memory disproportionately to the faculty of observation, to the detriment and overburdening of the memory.

Examinations will loom large in your horizon in the next few years. They are not pleasant things, but neither are they intrinsically distressful ordeals. It is the imagination of the student which sometimes makes them so. Some men occupy themselves so with anxiety about approaching examinations, with wishing they may pass, with thinking what they will do if they do or do not pass, that they have no time for that work which can enable them to achieve success, and after failing perhaps they spend a month or two in mourning for themselves and in making an exhaustive review of the shortcomings of examiners The man who passes an examination brilliantly is to be envied. The man who, having been refused in spite of his best efforts, triumphs over his disappointment not permitting the weight of it to bend him one hair-breadth from his purpose, is even more to be envied.

To-morrow the librarian will sell many note-books. The penny note-book with its frail binding is the worst bargain; the note-book should be small and neat, and the name and address of the owner should be written in it. It will be required for some time. it must be easily carried about, and it is going to be of considerable value. Each note should be short and should contain the substance of a thought without much elaboration. It is to be used as a cue to reflection and mental repetition, not as a substitute for the text-book. The value of a note is very small unless it is read over and mastered while the connexions and perspectives given by the teacher are fresh in the student's mind. The beginning of each evening's work should be an overhauling, patching up, and mending of the day's notes, and to facilitate this notes should not be crowded together. Some note-books are embellished with names of many authorities The habit of connecting ideas with their authors is a graceful accomplishment and is believed to produce a "positive emotional state" in the nervous systems of the brotherhood of examiners in physiology. My own efforts in this direction were not without success, for I remember coupling together, as the joint authors of an excellent new piece of work, the great names of Hallam and Brown-Séquard. I can vouch for the emotional state of my examiners who in a kindly manner made it known to me for how many years horses had grazed upon the turf which covers all that is mortal of the once inquisitive Hallam.

The question of choosing the course to be followed in the matter of examinations has, perhaps, not been definitely decided by all of you. It is prudent not to expect, or rely upon, any considerable changes in the relative value of the various qualifications in the immediate future, but to base your choice upon the present conditions. The nature of the qualifications which the beginner is to select must depend upon his purse, his industry, and his ambition. If any one of you is hesitating as to the course to follow in this matter let me urge him to [illegible] qualifications. *No examination is so* [illegible] as to be beyond the power of an ordinary intellect, nor is the least successful effort without some reward. "All that I strove to be and was not comforts me," said a great man. When you are settled in practice and known by your work you will be sought for and loved and trusted by the public for your personal worth, and it will matter very little whether you are entitled to wear a hood or a red gown. But in the difficult early days of life's march it is a very great advantage to ride under a grand and imposing banner.

However engrossed in his work the good student may be he does not neglect his personal physiology and anatomy but goes in heartily for sports and exercise. The majority of our gold medalists and of our best house surgeons have been keen sportsmen. When to-morrow you begin work in the school remember that you are putting in the foundations of that house which is to last you your life and that upon their thoroughness will depend the value of their more imposing superstructure. Above all things do not devote yourselves too exclusively to any one subject. Be good men "all round." Do not decide upon taking up for your life work any one branch of the profession until you are qualified, and do not imagine that there is not scope for your genius in any subject; that a particular branch of medicine or surgery is limited and that finality has been reached is a belief which time is continually upsetting. Here is a good example. In Erichsen's great work and in the seventh edition published in 1877 we may read: "When we reflect upon the triumphs of the surgeon's art ...... we can scarcely believe otherwise than that little remains for the daring to devise or the skill of the most dexterous to accomplish in the extension of that art in the direction of its operative department, and that the *surgeon must in future* be content to repeat, though possibly in a modified manner, those operations which have been inaugurated by the genius and perfected by the skill of his predecessors." In that edition there is not mentioned a single operation upon the kidney. And there are no higher and no lower branches of the profession. There are two ranks in the profession. The first includes all those who benefit the world by adding new knowledge; the second rank all of the rest of us who apply old and new knowledge to the immediate needs of mankind.

In the course of your work you will have much to do with the London poor. They are perhaps the most intelligent and interesting poor people in the world. There is nothing picturesque about them, the uncleanness of some of them will shock you, and the respect in which you hold mankind may be in danger of falling. Indeed, if you are sufficiently ignorant of the influence of *environment* upon the good and bad qualities of man it may be an effort to sympathise thoroughly with all their misfortunes. But look at that poor woman who came in the other day with so many evidences of a miserable life voyage; she is dying and as you feel her failing pulse, she fumbles for a handkerchief to save your fingers from being offended with the cold sweat of death. That little child upon the operating table for the second time is a common little slum child, but she looks into your face and says, "Kiss me first, doctor," and you suddenly think of your own sister. As you come to know your patients you will see among them much that is heroic—such fortitude and patience and self-denial as you feel yourselves incapable of, and you will not blush to think that they are fellow-men. Medical students have always been the good genii of the hospital patients. The poor of

I

is done for them I do not think this is the case It is more true that, as a rule, they are not demonstrative This story was told me yesterday An old and rare eight dollar American gold piece was sent as a gift to a hospital Being an unusual kind of donation inquiries were made and the giver was found to be an old hospital patient It was a poor woman who was suffering from a incurable disease The coin had years before been given her by her mother and now, being unable to earn a living and feeling the pinch of poverty, the temptation to sell the coin came upon her, and to resist what seemed to her an impiety she gave her one treasure to that charity which we may be sure she loved and trusted most

I had reached this point in my discourse and had called to mind other stories and had arranged that each succeeding one should be more pathetic than the last when—and I dare-say you are very glad for it—I was interrupted by a call to the hospital To return home I took a cab The cabman thrashed the horse I remonstrated, irritatingly enough, I daresay The cabman repeated his cruelty I got out "'E's such an awkward 'orse," said he, "no one can't do no good with 'im" Now at this stage I ought to have turned on my heel, but foolishly I returned to the charge It was not met "Yes, sir, you're quite right, I ain't got no mercy on 'im," admitted the cabman, and I thought I had begun to score "But, cabman," I said, "if you are so cruel you will surely want a great deal of mercy yourself when you come to die" "I don't know, sir," said he, "as long as it ain't at St Mary's 'Ospital and under the care of Mr Collier I might do without" There was something familiar to me in the man's voice, and though the night was dark I thought I recognised one of my oldest and most regular out patients His chuckle was hearty and his "good night" was kindly, and I have seen him here since

Are you to be congratulated upon your choice of a profession? Certainly not, if you only care for riches and power and yourselves; certainly n
ease loving recluse Yes, if you
you love mankind and the throb
minds not being made up, you may say 'Well, but the profession sees so much of the bad side of human nature" True, experience will early rob you of many pleasing illusions, but you will also see more of the good side of humanity than most other people You will see more of man as he really is, without the disguise—often disfiguring—in which modern civilisation wraps him "And," you may continue, "one will have to come in contact with all classes of society' Yes, and you will see in each the proofs of man's high destiny "But is the work of the profession appreciated by the laity?" I think I can give you a good answer You have read of the great plague of London and how the people fled to Highgate, Hampstead, and Finchley, and the city was for a long time ruined and deserted And now the same enemy is knocking at our gates I do
ng papers that the good people of
their workshops and fleeing to the
of the citizens at the present time
is not the false trust that plague cannot spread widely in a modern city, but their confidence in that power of defence which medical knowledge alone can give The plague will not frighten them All that the townsmen will do will be to pull down and sweep away those nasty relics of times in which the science of preventive medicine was practically unknown and to reward, right well we may be sure, the splendid work which the health officers have done

And about your prospects? As we face the hill which all of us must climb it must be admitted that it has a rather harsh face and seems to be high and steep, but all of us, I believe, will sooner or later reach a table land of modest prosperity or, at any rate contentment Are there too many men in the profession? From the point of view of suffering humanity are there too many? Are all the sick well cared for? Are there too many workers in the field of research? Is all that is possible being done for the protection of our children from tubercle? Is the stamping out of rabies a quixotic achievement not to be imitated? Is the Royal Army Medical Corps overcrowded? Are none of us over-worked? But from the point of view of a livelihood—aye, there's the rub Let us hope that time—which mends all things—may hurry up in this business

I have now only to wish you as good a time as I have had May you meet with as much kindness and forbearance as you

nected with it become as dear to you as to me May I, on behalf of the staff and the students, thank you ladies for your presence We know how important it is that the armour of our young warriors should be buckled on by your
a surgeon gives a non-
his art, he should pay
uses of those great
blessings anæsthetics and antiseptics. I would do so and would link with them one more discoverer, Miss Nightingale, who discovered the modern nurse

ST GEORGE S HOSPITAL

INTRODUCTORY ADDRESS BY F G, PENROSE, M D, F R C P LOND PHYSICIAN TO AND LECTURER ON MEDICINE AT, THE HOSPITAL

DR PENROSE began his address by offering a welcome on behalf of his colleagues to those who were joining the school for the first time He mentioned some of the vacancies which death had caused in the ranks of the governors of the hospital, referring particularly to the Duke of Westminster, Lord Clifden, and Mr George Shaw Stewart Speaking of the changes amongst the teachers in the school Dr Penrose mentioned especially the elevation of Mr Warrington Haward to the consulting staff and said how much he would be missed from the active work of the wards and the school He congratulated Dr W S Lazarus Barlow, who had resigned the curatorship of the museum, on his appointment to the charge of the clinical laboratories which had recently been opened at the Westminster Hospital He spoke of the gain to the hospital and school by the appointment of Mr H S Pendlebury as an assistant surgeon In alluding to the reconstitution of the University of London Dr Penrose said that it had been recognised for the past 20 years that the original institution was a university in name only, almost its only function being that of an examining body (a work which it had performed admirably), but that it did not in any way fill the position that the university of this metropolis should fill It might be hoped that, as newly organised, it would become the centre of the highest learning and the best teaching and that it might attract workers in all kinds of research, whilst still maintaining the high standard in its examinations and in the control of education that the old institution had done He hoped that one good result would be a reduction in the number of examinations which the future student would have to pass in order to obtain his qualifications and degree He thought that a primary, an intermediate, and a final examination would be quite sufficient to satisfy all necessary requirements The rest of Dr. Penrose s address was devoted to a consideration of some of the problems of medical education He said that at the present time, owing to the immense range of the subjects included under the term "medicine"—using the term in its broadest sense—and the minute subdivisions of the practice into numerous special branches, he thought that the best way was to ensure that students should be thoroughly grounded in the principles and technique of the chief sciences on which medicine and surgery were founded These he considered to be anatomy, biology, chemistry, and physiology The importance of a practical acquaintance with two of these sciences—viz, human anatomy and physiology—was already provided for As there were only two years available for the study of the fundamental sciences the time that could be devoted to biology and chemistry was very limited Dr Penrose thought that chemistry, particularly those branches which were known as physiological and pathological chemistry, were of such importance that he would like every student of medicine to have the opportunity of acquiring as thorough a practical knowledge of these subjects in the laboratory as he had of learning human anatomy in the dissecting-room. In order to make this possible he suggested that three years at least should be allotted to the subjects above-mentioned. He also looked forward to the establishment of a clinical laboratory which would provide men with an opportunity of following up chemical and other problems arising directly out of the work in the wards. Dr. Penrose alluded to the feeling which was held by some people that the subscriptions and donations to a hospital should be used only for the care and treatment of the patients, which feeling, he felt, was worthy of all respect, though he did not entirely agree with it. He quoted some remarks made by Lord Lister at the opening of the new laboratories at the Westminster Hospital in the early part of the summer[1] in support of those who considered that the funds of a charity might legitimately be spent in helping some forms of medical education and research. He thought that the subscribers should know exactly how the hospital funds were expended. He stated his belief that there were many wealthy philanthropic men in the country who would be willing to assist the hospitals and teaching schools by contributing directly to such objects, and he mentioned the munificent gift of Lord Iveagh to the Jenner Institute of Preventive Medicine as an example. Finally, he endeavoured to show that the remarkable advances that had been made in medicine and surgery during the past quarter of a century were due to a combination of work done in the laboratory and in the ward, yet the greatest results had come from the former rather than from the latter.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

INTRODUCTORY ADDRESS BY MISS L. B. ALDRICH-BLAKE, M.D., M.S. LOND.

MISS ALDRICH-BLAKE said: My most pleasant duty is to welcome, in the name of the London School of Medicine for Women, those students who to-day begin their life here. I chose for the subject of this opening address: Our Common Work, the Preparation for the Practice of the Profession of Medicine.

One great advantage of our profession as a field for our energies is the large number of faculties which may, and the considerable number which must, be cultivated in order that we may be even passable disciples of that science and art. Every good quality, either of intellect or character, can find scope in the daily life of a doctor, and those who have had the best opportunities for judging consider that the influence of character on the career is the greater. We need courage to attack difficulties, energy to overcome them, thoroughness to do our best in everything, and truth—which means accurate thinking as well as right speaking—and we must cultivate these qualities by every possible means. Bacon has said: "Since custome is the principall magistrate of man's life, let men by all means endeavour to obtain good customes. Certainly custome is most perfect when it beginneth in young years." We see that right habits are no less a public duty than a private duty, for Bacon continues: "But if the force of custome simple and separate be great, the force of custome copulate and conjoyned and collegiate is far greater. For there example teacheth, company comforteth, emulation quickeneth, glory raiseth, so as in such places the force of custome is in his exaltation." Therefore, both to the individual and to the school, the formation of right habits is of extreme importance.

A more difficult question is what are right customs in relation to the school, our work and our patients? This school was founded in 1874 and we now find ourselves established in a luxury of housing that is well to bear in mind as a thing to be grateful for. Our gratitude may best be shown by keeping alive in the school that spirit most conducive to good work. Some ancient has said: "What is not good for the hive is not good for the bee." As members of the school and afterwards as members of the medical profession, we can give thought to the whole without danger of swamping our individual interests. The influence of students upon one another is far greater than that which can possibly be exercised by the constituted authorities. It belongs to each one of you to make the spirit of this place worthy of its greater body. The spirit needed is of that nature which looks upon obstacles as things to be overcome. If some measure of public spirit has ruled your school life, medical etiquette, I think you will find, seldom requires of you more than the old maxim, "Do as you would be done by," would demand of any honourable person. "With regard to work," Dr. Arnold has said, "I suppose the desirable feeling to entertain is always to expect to succeed and never to think you have succeeded." Without hope work would, indeed, be a half-hearted sort of thing. Humility is a virtue, and perhaps the surprises of life are less apt to take a pleasant form for those whose estimate of their own worth is great than for those whose estimate is small, but beware of that humility which would paralyse honest effort. "Never to think you have succeeded" is quite as important. In the lives of all great men we cannot fail to be struck with the enormous energy with which they pursue their work, one thing leading to another—an energy which in our small way we ought to exercise, feeling that anything which we have attained is only an opportunity to do something further. You are preparing for a profession in which learning must continue as long as life lasts and for which self-instruction and self-reliance are absolutely essential. As Herbert Spencer has said: "It is not the knowledge stored up as intellectual fat which is of value, but that which has been converted into intellectual muscle." Now, though good teaching is absolutely essential, mere recipients of knowledge do not acquire the power of attacking new subjects on their own account. The difference between being educated and being crammed is that in the former the powers of observation and reflection are developed, whereas in the latter the mind is more passive and the brain is expected to receive an undue quantity of predigested matter to be retained as best it may. The great increase in the facilities for practical work compensates somewhat for the far larger ground which has to be gone over. Your course is accurately mapped out for you, but the liberty of doing or not doing your individual best always remains to you. Learn your anatomy, physiology, &c., not merely on account of examinations, but because your after-work requires that knowledge.

Cultivate by every means in your power habits of patient and accurate observation. A diagnosis does not mean the mere fitting of a disease with its name—what you want is a just view of the whole condition of the patient. Sir James Paget once said that it would be interesting if someone wrote a history, not of discovery but of oversights. He says: "We never pass a month, never a week, without finding observations made, discoveries made by persons at work in the same field that we are, or suppose ourselves to be, at work. And why do we not see these things? Surely, that these persons should have seen them clearly and that a crowd of others should not have observed them at all must be a proof that the crowd was either very careless or very idle, or really it was a proof that observation is very difficult and not to be acquired except by the most careful study and self-discipline." Opportunities for such study are yours if you will but use them. Attend all class examinations, for writing upon a subject shows how vague and indistinct are many impressions which we take for knowledge and attendance at these minor trials cultivates in one that most valuable quality, presence of mind. Do not be too much afraid of making mistakes. If on this account you avoid answering a question you waste a valuable opportunity of getting the correct solution impressed on your mind. Cultivate the habit of rapid reasoning, so that your answer, whether right or wrong, instead of being a mere guess has some real basis in your mind. The two chief sources of mistakes are ignorance and carelessness; if you avoid the latter the former will largely cure itself. Carelessness in work must be to us an unpardonable sin, and thoroughness in its widest sense must be our highest aim. Whatever duties we undertake let us remember that they are ours to fulfil to the best of our ability and that they ought not lightly to be given up because something better presents itself. Experience, valuable as it is, will be found to be dearly bought at the expense of a reputation for reliability.

In the treatment of the patient lies the test of the success of our education and none of you will imagine that treatment begins and ends with the presentation of a suitable prescription. If you are to be as useful as possible you must keep in mind the fact that you have to treat an individual and not a type, and that the wide knowledge which is only to be obtained by real study of human nature will enable you to do this successfully. There is no incompatibility whatever between science and that which one might call wisdom, but both are needed. Remember that your object is to heal. You must never give avoidable pain, either by touch, speech, or manner, and because you *will be obliged to do much that must necessarily give pain* be the more careful never to do so needlessly. However little a patient may be able to estimate your intellectual and technical attainments any one of them can appreciate your kindness. To be broad-minded, thorough, kind: the saying of it is easy, the doing will last us all our lives.

---

ROYAL VETERINARY COLLEGE.

INTRODUCTORY ADDRESS BY PROFESSOR JOHN MCFADYEAN, M.B., C.M., F.R.S. EDIN., PROFESSOR OF COMPARATIVE PATHOLOGY AND BACTERIOLOGY AT THE COLLEGE.

AFTER referring to some of the principal events of the preceding session the lecturer observed that the occasion was in one respect a very special one, inasmuch as they stood at the close of the century which embraced almost the whole of the past history of the veterinary profession in Great Britain. From time immemorial man had endeavoured to interfere with the course of disease in the animals which he had domesticated, but the foundation of the oldest European veterinary colleges during the latter half of the eighteenth century was the real birth of veterinary science. 100 years ago the Royal Veterinary College was only in the tenth year [illegible] changes had come over [illegible] study of the methods [illegible] and knowledge in- [illegible] luable lessons for the members of the profession at the present day.

Referring in the first place to the growth of knowledge *regarding the causes of disease Professor McFadyean* instanced the cases of glanders and tuberculosis. At the beginning of the century the fact that glanders was con- [illegible] country, but it was [illegible] hat way. Coleman, [illegible] the first 39 years of the century, believed that the disease was more frequently generated than caught. Such a belief was never justified, and it only appeared to be so because outbreaks of the disease not infrequently occurred in stables into which no horse showing any symptom of glanders had ever been admitted and because it often broke out during or at the end of a voyage among horses that appeared to be perfectly healthy at the time when they were shipped. These were actual facts, of which illustrations continued to occur at the present time, but they did not prove or even make probable the spontaneous origin of glanders. One of the premisses necessary to justify the conclusion had been erroneously assumed to be true—viz., that the apparently healthy horses among which the disease broke out were all free from glanders. When large cargoes of horses were shipped over sea the disease often broke out among them simply because glanders was a very common disease throughout the whole of Europe and because many glandered horses retained for considerable periods the appearance of perfect [illegible] latter truth *neither* ger [illegible] All that was required [illegible] examination, which cou [illegible] glanderous lesions in many cases in which the horse showed no symptoms of the disease during life.

Judging from the literature of the time tuberculosis as a disease of the lower animals did not appear to have attracted much attention [illegible] in this country during the c [illegible] but when it came to be [illegible] common disease among cattl [illegible] then prevalent regarding human consumption, including a firm belief in its inheritance. As recently as 20 years ago [illegible] reditary [illegible] It was [illegible] of that view had been generally recognised. This belief was shattered (1) by recognition of the fact that contagion was at least one of the modes of origin of the disease, and (2) by careful post-mortem examination of the new-born calves of tuberculous cows. Observations of the latter kind had shown that except in comparatively rare instances the progeny of tuberculous cows came into the world without any trace of the disease in any of their organs, and recognition of the contagious nature of the disease made it almost absurd to ascribe its greater frequency in *particular families to congenital transmission.* The natural and correct interpretation of the facts was that the greater frequency of tuberculosis among the progeny of those who were themselves visibly affected with the disease was due to the offspring being almost invariably born into a place in which they were afterwards constantly exposed to the risk of infection. These and many other instances emphasised the importance of painstaking investigation along the lines of clinical observation and post-mortem examination. At the same time it was important to notice that the great majority of the discoveries of the century regarding the causes of disease had been made, not by greater assiduity in the collecting of clinical observations or in recording the appearances revealed by post-mortem examination, but by the application of new methods of research in which the use of the microscope, the artificial cultivation of bacteria, and experimentation with animals had played the chief part. It was difficult to apportion to each of these three methods of research the credit that belonged to it, mainly because they had usually been employed in combination. Immense strides in pathology had undoubtedly been made simply by the microscopical examination of diseased tissues, and a large part of their knowledge of the disease-producing bacteria had been acquired independently of experiment on the living animal, but no honest person acquainted with the facts could deny that they now knew much that was of the highest practical importance regarding both human and animal diseases of which they would still have been ignorant had experimentation on living animals been a forbidden method of investigation.

Discoveries which threw new light on the cause and nature *of disease necessarily influenced methods of treatment* and prevention, and the past century had witnessed great changes in the means adopted to counteract disease. There was no lack of alleged remedies at the beginning of the century, but many methods of treatment in which their [illegible] almost [illegible] There [illegible] ts than [illegible] l make them careful in estimating the effect of remedies in their own time. Blistering and firing were still much practised, and it might be said that they had stood the test of the century, but it was perhaps permissible to suggest that the clinical *evidence even of a* century might not be conclusive in such a question. At the time when every patient, human and equine, was bled and physicked there was no evidence as to the merits of less vigorous treatment, and so at the present day it might with much truth be said that the alleged overwhelming evidence in favour of firing and blistering was no evidence at all. Thousands of horses were fired and blistered (which involved a period of rest); many got well or were improved, and the result was set down to the credit of the counter-irritation. But at the present time no one with any considerable practice dared to treat his sprains, splints, and spavins by simple rest without blistering or firing, and neither the past nor the present furnished the *necessary data* from which to estimate the therapeutic value of severe counter-irritation.

They were, perhaps, entitled to regard as one of the advances of the century that they were more inclined than their forefathers to credit the sick or wounded animal with greater natural powers of recovery, and a fuller knowledge of pathology had done much to restrict the administration of internal medicines and to *emphasise the importance of all* that is included under the term "hygiene." They had come to recognise that not a few of the things that were at one time viewed as being themselves the essence of disease were in reality processes of defence or repair and did not require any repression by medication. When the cause of disease had been removed medicinal substances could do little or nothing to hurry nature in the process of repair, and great care should be exercised before saying of any drug that "if it did no good it could do no harm."

ANEURYSM OF THE RENAL ARTERY.

BY HENRY MORRIS,
VICE-PRESIDENT, AND CHAIRMAN OF THE COURT OF EXAMINERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; SURGEON TO THE MIDDLESEX HOSPITAL.

TRAUMATIC aneurysm is one of the consequences of injury to the pedicle of the kidney, but aneurysms of the renal artery and its branches also occur in man from causes other than injury. They have been met with likewise in the horse. In the human subject, however, renal aneurysms, whether traumatic or spontaneous, are amongst the rarest of all aneurysms. Two varieties are found after injuries: (1) small sacciform aneurysm, the walls of which are formed by some or all the coats of the artery; and (2) large, false aneurysm, the walls of which are composed of the condensed fibrous tissue developed around the extravasated and coagulated blood, and with which the surrounding organs and tissues become more or less firmly matted.

A false aneurysm has in some cases gone on growing for years and has ultimately attained an enormous size, as in the case under my care, which I report further on, and in which the tumour occupied half the abdomen. They develop in three ways—namely: (1) by the giving way of a small, true aneurysm, which may be either of spontaneous or traumatic origin; (2) by the yielding of a thrombus which temporarily closed a ruptured artery; and (3) by the immediate outpouring of blood from a ruptured artery.

A true aneurysm—always apparently of small size—if of traumatic origin may be associated with an extravasation of blood or urine or of blood and urine, both aneurysm and extravasation being the consequences of the same accident. One such case at least is on record (Reeves's). In this case the swelling detected during life was caused by the extravasation of blood and urine around the contused and lacerated kidney; the tumour was what some surgeons would describe as a false hydro-hæmato-nephrosis. The small aneurysm was a post-mortem coincidence and had no bearing on the cause of death, but none the less appears to have been an interesting and rare result of the injury.

A true aneurysm may be associated with a false aneurysm and both may be the direct results of the same accident. Thus, a small sacciform aneurysm may be situated on the renal artery and the artery or one of its branches may be torn across or lacerated further on and there open into the false aneurysmal sac. Such was the condition in Hilton's case.

TRUE ANEURYSM OF TRAUMATIC ORIGIN ASSOCIATED WITH FALSE HYDRO HÆMATO NEPHROSIS.

An instance of the sacciform variety was referred to in my book "Surgical Diseases of the Kidney," 1884, as Reeves's case. It is the same case as that published by the late Dr. F. C Turner.[1] It occurred in a lad, aged 19 years, who was thrown out of a cart on May 13th, 1884. Hæmaturia occurred from the sixth day onwards, being particularly profuse on the twenty-second and twenty-seventh days. There was pain in the right side with vomiting and irregular pyrexia of a hectic type. On June 10th—i.e., on the twenty-eighth day after the injury—a swelling appeared in the right loin and the lad died on June 13th. There were blood and inflammatory lymph in the peritoneal cavity and a hæmatoma in the right loin. The right kidney, which was entirely separated from its capsule, lay in a hæmorrhagic cyst filled up with disintegrated blood-clot; the kidney substance was disorganised except a small portion at the lower pole. The calyces were ulcerated and contained puriform fluid and communicated as did also the renal pelvis with the perinephric cavity. On the posterior surface of this kidney, near the hilum, was a well-defined encapsulated blood-clot of round outline and of the size of a cherry attached to the central branch of the renal artery, about half an inch from the point of division of the arterial trunk. The seventh and eighth ribs were fractured on the right side. There was blood-clot in the bladder and areas of suppuration were found in the cortical portion of the left kidney.

In this case the swelling detected during life was caused by the extravasation of blood and urine around the contused and lacerated kidney—it was what some surgeons would describe as a false [illegible] death was the disorg[illegible] nephritis of the oth[illegible]. The aneurysm was a coincidence in the case, but none the less a very rare and interesting result of the injury.

This and the following are the only cases of small sacciform traumatic aneurysm of which I know. Whether—if the injury to the kidney in these cases had been less severe and the patients had lived—the small aneurysms would have become cured, or remained stationary, or, preserving their true sac-like type, would have increased in size, or would have ultimately ruptured and led to a large false aneurysm, it is impossible to say.

TRUE ANEURYSM OF TRAUMATIC ORIGIN ASSOCIATED WITH FALSE ANEURYSM DUE TO RUPTURE OF THE ARTERY AND NOT OF THE SACCIFORM ANEURYSM.

The following case (referred to in my book) is also an illustration of a true sacciform aneurysm of traumatic origin. A man, aged 21 years, who had been struck by the buffer of an engine, was admitted into Guy's Hospital, under the care of Hilton,[2] on June 20th, 1866. On admission he vomited and complained of great pain in the abdomen just beneath the ribs which was aggravated on the slightest pressure; the next morning the vomiting and pain continued, but he was able to walk to the closet, where he passed both urine and fæces. On the day following the injury the catheter had to be passed and one and a half pints of bloody urine were withdrawn. Some improvement followed on the fourth and fifth days, but on the eighth there was an increased quantity of blood in the urine. From the fourteenth day till his death clots of blood accumulated in the bladder and gave rise to agonising pain in the hypogastrium and at the end of the penis. A dull swelling formed in the left side of the abdomen, tympanites and delirium supervened, and the patient died on the twenty sixth day. The left kidney was found to be ruptured across the middle and the lower segment was cracked transversely by numerous minute fissures. The left ureter and a branch of the left renal artery, on which was a small recent aneursym, opened into a large cavity surrounding the broken kidney, and was filled with grumous and vilely offensive blood-clot and urine. The renal vein was not injured. In the peritoneum, forming the anterior wall of this cavity, there was a ragged rent in a thin slough, through which offensive bloody serum was found to exude into the peritoneal sac. No positive evidence of peritonitis existed.

In this case though the branch of the renal artery upon which the aneurysm was situated opened into a large space containing blood-clot and urine, it would appear that the small sacciform aneurysm had not yielded and did not itself communicate directly with the false aneurysmal sac.

FALSE ANEURYSM DUE TO THE BURSTING OF A SACCIFORM ANEURYSM.

CASE 1.—An example of a large traumatic false aneurysm originating from a true aneurysm of the left renal artery was published in 1891 by Grüber.[3] The subject was a workman, aged 39 years, who was admitted into the Rochus Hospital on Dec. 14th, 1890, eight months after falling from a height of two metres and striking his back against a box. Great dyspnœa and great pain in the left loin immediately followed the injury and half an hour later his urine contained blood, and blood-clots of indefinite shape were passed during the next two days. For three months he suffered much pain in the loin, but there was no further hæmaturia; then without known cause hæmorrhages recurred on several occasions. On admission there was a tumour in the left hypochondrium which reached downwards into the false pelvis and inwards two fingers' breadth beyond the median line. This tumour was dull on percussion, of a soft solid consistence, smooth in outline, tender on pressure, and non-adherent to the abdominal wall. It did not pulsate and gave no auscultatory sign. Micturition was very frequent and there was hæmaturia which was aggravated by exercise. The symptoms increased and the man became very cachetic and died paraplegic in the beginning of February, 1891. At the post-mortem examination there was found a sac 20 centimetres by 12 centimetres. Where the left renal artery entered this sac it was dilated to the size of a child's fist.

renal artery.

In this case the history is consistent with the post-mortem appearances: a fall followed by severe pain in the loin and [illegible] continuance of pain in the loin, [illegible] or three months; then when the [illegible] ecurrence of hæmorrhage and the [illegible] a tumour.

CASE 2.—Oestreich has published[4] a case which he described [illegible] aneurysm of the left renal artery, [illegible] onic endarteritis. It occurred [illegible] he fell in an unconscious state [illegible] February, 1891. Two months afterwards there was hæmorrhage, presumably from the left kidney, which daily became worse. On admission, three months or rather more after the fall, a large tumour was detected in the left renal region and the bladder was distended with a large quantity of clot and fluid blood. Death ensued three days later. At the post-mortem examination a large mass of laminated clot surrounded with layers of fresh blood-clot was found behind the peritoneum around the left kidney and descending colon. It was partly in the parenchyma of the lower end of the kidney and partly in the surrounding tissues, and was in communication with the renal pelvis. The branches of the renal artery were markedly dilated and tortuous.

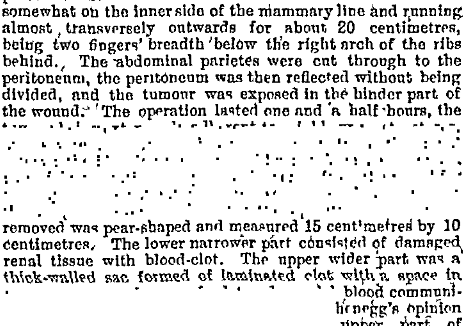
Daniel Nebel[5] describes a case of aneurysm of the aorta involving both renal arteries in a man over 30 years of age who had had his right testicle removed for malignant disease, both the disease of the testicle and the aneurysm being ascribed to a fall from a horse.

CASE 3.—He then goes on to relate briefly a case (probably of this variety) of renal aneurysm in a medical man who, in November, 1717, four years after falling from a horse on to his left side, experienced vehement pain and pulsation on the left side of the abdomen. The case was diagnosed as an aneurysm. At the post mortem examination a tumour of the size of the head of a child three years old was connected with the left kidney, which itself was flaccid and putrid. This aneurysm had burst into the peritoneum, causing sudden death. A large quantity of blood was found in the peritoneal cavity. The aorta above and below the aneurysm as well as the vena cava and its branches were empty of blood. In the wall of the aneurysm was an opening capable of admitting two fingers, and through this the large amount of blood found in the peritoneum had escaped.

A case of traumatic aneurysm is referred to by Titius (S.O.) in "De renum vitiis: Aneurysmatis arteriæ Renalis sinistræ exemplum, 1798, Vitebergæ." It occurred in the person of a medical man and resulted from a fall from a horse. No details, however, are given beyond the statement that it involved the left renal artery and proved fatal after four years. There seems to be good reason for considering this as merely a reference by Titius to Daniel Nebel's case.

FALSE ANEURYSM DUE TO YIELDING OF A THROMBUS IN A *RUPTURED ARTERY.*

Julius Hochenegg[6] reported a case of traumatic aneurysm of the right renal artery which is pretty certainly an example of a false aneurysm due to the yielding of a thrombus which for a time closed a rupture of the renal artery.[7] A gardener, aged 51 years, on April 19th, 1889, fell from a ladder a height of three metres, striking his right lumbar region violently against the upright of the ladder. H[illegible] pain in this loin and a[illegible] passed about a quarter o[illegible] spite of absolute rest, ergotin injections, and the application of cold, bleeding persisted for three days, but on the fourth it stopped. Recovery was slow. A month later, copious hæmorrhage lasting a week was followed by very severe cystitis for a fortnight. Two months later still the patient was dismissed as cured. Four months later after great exertion profuse hæmorrhage recurred and continued for three days, during which he lost three litres of blood. Recovery was again slow and this time imperfect. Previously to this time which was elastic, painless, and moveable, and of the size of two fists, was discovered in the right lumbar region. After another three months a further recurrence of hæmaturia occurred for which he rested two months in bed; and again after an interval of rather more than three months hæmorrhage returr[illegible] frequent and the [illegible] In the intervals [illegible] was normal or sho[illegible] tion a tumour la[illegible] right hypochondriu[illegible] on pressure and ch[illegible] It had a smooth [illegible] tinctly, but at the time of operation when the tumour was exposed no pulsation could be detected. Dr. Kunz now diagnosed a lesion of the kidney or a traumatic aneurysm of the renal artery and sent the man to Albert of Vienna[8] who removed [illegible] i.e., nearly t[illegible] placed on hi[illegible] somewhat on the inner side of the mammary line and running almost transversely outwards for about 20 centimetres, being two fingers' breadth below the right arch of the ribs behind. The abdominal parietes were cut through to the peritoneum, the peritoneum was then reflected without being divided, and the tumour was exposed in the hinder part of the wound. The operation lasted one and a half hours, the [illegible] removed was pear-shaped and measured 15 centimetres by 10 centimetres. The lower narrower part consisted of damaged renal tissue with blood-clot. The upper wider part was a thick-walled sac formed of laminated clot with a space in [illegible] blood communi[illegible]henegg's opinion [illegible] upper part of [illegible] red within the [illegible] at this led to the gradual development of the aneurysm. This view was considered to be supported by the specimen which shows the remnant of the kidney and the aneurysmal sac covered by the same capsule. (See Figure.)



Reproduced by Butterworth from the figure in Hochenegg's paper. Aneurysm of renal artery with kidney, removed during life by Albert of Vienna. A, Capsule. B, White laminated clot. C, Cavity. D, Kidney.

In this case the violent hæmaturia which occurred immediately after the accident indicated the rupture of a large vessel. The cessation of the hæmorrhage after a few days, the intervals of a month, two months, and four months between the recurrent hæmorrhages, and the non-appearance of a tumour in the lumbar region until seven months after the injury, suggest that the rent in the artery was from time to time closed by clot which ultimately gave away altogether and allowed of the growth of the aneurysm. If Hochenegg's view is correct that the artery was ruptured within the kidney the resistance offered by the renal substance and by the renal capsule may have delayed the development of a tumour.

FALSE ANEURYSM FOLLOWING IMMEDIATELY ON THE WOUND OF THE ARTERY.

The six following cases are examples of false aneurysm developing as an immediate result of a laceration of a branch of the renal artery, and not by the giving way of a true sacciform aneurysm or by the yielding of a thrombus which for a time closed a rent in the artery. Two of them (probably three) might also be described as false hæmato-nephroses, the third as a false aneurysm within the renal capsule; the fourth and fifth were true hæmato-nephroses.

CASE 1.—Hahn[9] reports the case of a large traumatic aneurysm of the left renal artery upon which he successfully operated. It occurred in a woman, aged 49 years, who in March, 1893, fell down several steps. She at once experienced a sudden sensation as if a ball were moving in the abdomen and she felt a lump under the border of the ribs on the left side. When admitted into hospital on May 2nd, 1893, there was a tumour of the size of a child's head in the left side of the abdomen; it was smooth, well-defined, elastic, and dull on percussion. It extended vertically from the costal margin to a hand's breadth below the level of the umbilicus and inwards to within three fingers' breadth of the linea alba. The tumour did not move with respiration or with change of posture, but could be moved between the hands on bimanual examination. There was no pulsation. The urine was normal. The diagnosis was considered to lie between hydro-nephrosis and a soft renal new growth. On May 8th the kidney was exposed by an oblique incision in the loin and appeared to be normal. On puncturing the tumour only blood escaped and on attempting to detach the lower end of the tumour a sudden profuse hæmorrhage occurred. The wound was then packed, the patient was turned on to her back, and an incision was made over the front of the tumour. On tearing through the capsule dark brown coagulum was found, but only a little fluid blood escaped. The tumour was removed after ligaturing the pedicle of the kidney. The operation lasted one and a half hours. Recovery ensued. On examining the specimen after removal it was found that the aneurysm was entirely separate from the kidney but was ensheathed in the same covering. The upper part of the kidney was normal; the lower end was atrophic and flattened. A branch of the renal artery communicated with the cavity.

The immediate development of a tumour in the left renal region and the woman's instantaneous sensation as if a ball were moving in the abdomen indicate that the ruptured artery at once discharged a considerable quantity of blood and that the formation of a false aneurysm was a primary result of the rupture.

CASE 2.—The following case occurred at the beginning of this year in my own practice. A farmer, aged 36 years, slipped and fell, striking his left side against the top of a low wall. This occurred five years before he came under my charge. Immediately after the accident he felt pain in his side and passed blood in his urine. Ruptured kidney was diagnosed by Dr. Sutton Pratt of Rugby, and for five months the patient kept his bed. During the whole of that time he was passing blood in his urine in the following way. A considerable quantity of blood with blood-clots was passed at intervals of a fortnight just for a single micturition but in the intervals the urine was merely blood-stained. Whilst keeping his bed he noticed that his ribs on the left side became bulged forwards, but no particular attention was given to this as he had no pain. At the end of six months after the accident the patient gradually resumed his occupations as a farmer and continued to do so almost to the time of my seeing him. For the last three years especially he thought his side had been getting larger and harder. For a period of two weeks during the last month prior to admission under me on Feb. 5th, 1900, he had kept his bed on account of pain in his left groin and thigh. On admission he complained of pain in the left groin, the left side of the scrotum, and the left sacro-iliac joint. His urine was normal except for an occasional very slight trace of blood. The temperature was normal. On inspection the whole left side of the abdomen, the lower part of the left side of the thorax, and the left loin were bulged by a tumour which was very hard and uniformly so, smooth, quite fixed, dull, non-fluctuating, and not tender, though of late somewhat painful. This tumour extended from the sixth rib in the nipple line to two inches below the level of the umbilicus and reached inwards to the median line. Its most prominent part was in the nipple line at the costal margin. The skin over the tumour was normal or but slightly reddened. Neither Dr. Cayley nor I detected pulsation, but my colleague, Mr. John Murray, thought he could feel a faint pulsation of an expansile character. When some days later the patient was under chloroform a careful examination was made by Mr. Murray, Mr. T. H. Kellock, and myself, but no pulsation could then be detected. There was a loud systolic bruit over the tumour which was best heard in front. It did not extend along the vessels to the groins nor was there any difference in the beat of the common femoral arteries on the two sides. Of late the swelling had been increasing much more rapidly. The diagnosis was thought to lie between a large circum-renal hæmatoma and a renal new growth, and Mr. Murray, believing he detected pulsation, diagnosed it as a renal aneurysm. The early onset after the injury of the swelling, its slow increase in size, its uniform consistence, and extreme hardness and fixity seemed to favour the view that there had been extravasation, coagulation, and organisation of blood in the perinephric tissue, whilst its recent more rapid increase and the supervention of pain suggested that part of the mass was beginning to soften and break down.

The patient readily consented to an exploratory operation, and on Feb. 13th an oblique lumbar incision was made, part of the tumour was exposed and tapped with a small trocar and cannula, and a little reddish-brown serous-like fluid escaped. A small incision was then made through the wall of the tumour and a pair of closed hæmostatic forceps were thrust into its substance. A piece of the contents was seized and withdrawn and on examination this was found to be old discoloured blood-clot of a dirty brown colour. The incision in the tumour capsule was enlarged so as to admit two fingers, and some four or five ounces of dirty brown laminated clot were cautiously removed piecemeal. Then suddenly there rushed against my fingers a stream of warm fluid and simultaneously arterial blood flowed violently from the wound. The situation was tragically critical; it was clear that if such bleeding continued for but a few seconds life would be extinct. A large prominent tumour between the anterior abdominal wall and the spinal column made direct compressure of the aorta impossible, and several pounds' weight of blood-clot were between the opening in the sac of the tumour and the position of the renal artery. Instant action was imperative, yet to attempt to control the hæmorrhage by packing with gauze seemed like stuffing a hole in a sinking ship with tow. I therefore immediately forced my hand across the tumour cavity in the direction of the renal artery and compressed the inner wall of the tumour against the spinal column, whilst with my other hand I pressed firmly upon the front of the tumour through the anterior abdominal wall. By this means I controlled the hæmorrhage almost completely, but not absolutely. I at the same time requested my colleague, Mr. Murray, to extend the incision in the abdominal parietes downwards and forwards towards the groin without dividing the peritoneum and to reflect the peritoneum towards the median line until he could compress the abdominal aorta above the level of the renal artery. I then removed as quickly as possible all the blood-clot—most of which was old and laminated—from the interior of the sac and found the opening of the renal artery by seeing blood come from it in a large jet on releasing pressure. I seized the mouth of the vessel with a large pair of clamp forceps. All hæmorrhage was now absolutely stopped and I was able to proceed with the removal of the sac. As the patient's pulse was somewhat failing one and a half pints of saline solution were injected into a vein in the arm and a dose of strychnine was hypodermically injected. Meanwhile the sac was sufficiently detached from its connexion for a ligature to be passed round the renal artery on the proximal side of the sac and the whole of the anterior and lower parts and a part of the inner and of the posterior wall of the sac were removed.

The rest of the wall was so adherent, especially above to the under surface of the diaphragm, that it could not be detached. The sac extended very high up into the thorax and the spleen with the diaphragm was pushed up a long way. In trying to separate the upper and back part of the sac wall the peritoneum was torn and the lower surface of the spleen was exposed. The rent in the peritoneum was closed with a continuous suture. A small iodoform gauze drain was placed in the loin and made to project at the back of the incision. The parietal wound, which measured eight inches, was closed by interrupted sutures The limbs were bandaged and raised, and after removal to bed an enema of brandy, beef-tea, and egg was administered. Hot-water bottles were placed around the trunk and another subcutaneous injection of strychnine was given. The patient rallied and recovered consciousness about an hour after returning to bed. About four hours after the operation he wished to be turned on his side, but finding this position less easy he requested to be placed back again. Shortly afterwards he vomited; then his respiration seemed to fail and within an hour he died.

---

[9] Deutsche Medicinische Wochenschrift, August 9th, 1894, p. 637.

The blood-clot removed from the sac weighed several pounds and much of it was commencing to disintegrate. There seemed little room for doubting that had the case been left alone the sac would soon have broken through the peritoneum or diaphragm or have become the seat of suppuration The sac was composed of condensed fibrous tissue, and at one part of it a thin layer of scarcely recognisable kidney tissue formed part of its thickness. Microscopically, this was demonstrated to be renal parenchyma in a state of extreme chronic interstitial inflammation. There was no other trace of the left kidney, and neither in the tumour removed nor at the post-mortem examination was there any trace of the left suprarenal capsule.

At the necropsy there was no blood or free fluid in the peritoneal cavity, but two or three small extravasations of blood and a little recent blood-clot were seen behind the peritoneum in the left loin. The right kidney was healthy. The aorta and left renal artery were normal. A probe passed from the aorta along the trunk of the left renal artery was obstructed by the ligature around its distal extremity. A probe introduced into the left renal vein passed for several inches in the remnant of the wall of the sac but did not emerge into the cavity. The orifice of the renal artery where it opened into the aneurysm was large enough to admit a full-sized catheter. A part of the sac wall which had not been removed at the operation was so intimately incorporated with the under surface of the diaphragm that they could not be dissected apart.

CASE 3.- of the renal arte uppe,[10] is quoted Reins," tome iii., and cited by Bloch in his *Thèse de Paris* ("De la Contusion du Rein"), 1873. At Cadiz, on Oct. 28th, 1759, a robust young boatman, Pierre Veldhuisen, in entering his craft fell athwart the gunwale, the full force of the blow being concentrated on the right lumbar region. Severe pain, at this spot immediately ensued, which quite incapacitated him. An hour later a bruise as large as the palm of the hand was found at the seat of injury. He was bled from the arm twice within a few hours and a water dressing was applied to the side. The urine passed was highly charged with blood and the pain continued very severe. He was again bled and after a few days' quiet seemed to have completely recovered. Nine days after the accident, while getting into his bunk, he was seized with violent pain in the loin, became pale, faint, and emities and the apprehension of omen was then found by Rouppe the right side, but soft on the left. The patient soon became delirious and convulsed and died in ten hours with all the signs of hæmorrhage.

Rouppe made a necropsy the same day and found a hard dark mass, larger than an adult head, occupying the right half of the abdomen and formed by a retro-peritoneal hæmorrhage, in the midst of which, like the stone within a peach, lay a smaller and harder round mass. This smaller tumour was a multilocular sac, the several pouches of which were separated by membranous septa, and contained clot but of a firmer nature and laminated. The kidney was seen on laying open the sac of this second tumour surrounded by dark blood. On distending the renal artery with air some bubbles escaped just where the vessel entered the kidney, and on further examination the lesion was found just within the true capsule The blood had penetrated along the course of the vessels to the outer aspect of the kidney so that it entirely separated the capsule from the kidney substance, which itself was not found to have been penetrated.

This inclosure of a ruptured aneurysm or artery in a mass of blood-clot is a familiar experience in connexion with the most fruitful source of hæmorrhage in the lung—where the escaped blood collects and coagulates in a cavity around the vessel greatly obscuring its origin, but usually proving on careful search to be directly connected through the rent with other clot within its lumen.

CASE 4.—This was a case of traumatic aneurysm of the nature of a true hæmato-nephrosis: the orifice of the renal artery opened into the sac, all traces of pyramidal and cortical substance had disappeared, and there was a remittent tumour in the hypogastrium and left flank. The case is reported by M. Danyau, was commented upon by Rayer,[11] and was quoted in my book in 1884. A young workman, aged 15 years, was taken to the Hôtel Dieu in the early part of October, 1835; the anterior region of the left kidney had been contused against a counter; after this he passed blood with his urine. Some time afterwards, the hæmaturia for a while having ceased, he suddenly voided from three to four "palettes" of pure and bright blood. On Nov. 19th a remittent tumour was felt in the hypogastrium and left flank and seemed to be elongated in the direction of the ureter The bladder contained clots of blood; there was retention of urine, catheterism was very painful, and the tumour, without becoming more painful, was more prominent and larger. He died on Nov 26th. At the post-mortem examination the tumour consisted of the kidney, its pelvis, and the commencement of the ureter greatly distended and filled with a mass of black coagulum which had already commenced to decompose. There was no trace of either pyramidal or cortical substance of the kidney left; they had both disappeared as the result of intra-renal pressure caused by the effused blood. On examining the interior of the sac with care the orifice of a renal artery, plugged by a clot, was discovered. The walls of the tumour were formed by the fibrous tunic of the kidney and the condensed layers of the surrounding cellular tissue. The lower end of the left ureter and the kidney and ureter of the right side were healthy; the bladder was healthy and moderately distended with clear urine.

CASE 5.—Mounier[12] reported the following case of traumatic aneurysm within the renal capsule which he described as a "hæmato-nephrosis." A soldier, aged 25 years, was admitted on Jan. 20th, 1849, into the Val-de-Grâce military hospital three hours after having been knocked down by a handcart which passed across his abdomen from right to left at the umbilical line. He instantly felt the most agonising pain, which continued long after his admission and was accompanied by bilious vomiting, tympanites, and rapid respiration. The pain radiated over the whole abdomen, but at times was most marked in the left flank and left iliac fossa. On the second day the pain greatly abated and was limited to the left loin and left side. He went on improving up to the seventh day, when hæmaturia appeared and continued, but otherwise the patient was no worse. He had been getting up for several days when suddenly, on Feb. 9th (20 days after the accident), he was seized with the most violent pain in the left flank and with an intense desire to micturate, which, however, he was unable to accomplish. The next day there was only slight pain, increased, however, by pressure. As he had not passed urine naturally since the previous day a catheter was used and drew off one and a half litres of bloody urine Thus matters continued till Feb. 14th, when the lumbar pain increased. The hæmaturia resisted all treatment. The patient, enfeebled by the quantity of blood passed with the urine, by pain, and by the loss of blood from the frequent application of leeches, died on March 2nd, 41 days after the accident. No mention is made in the clinical account of the case of any tumour having been detected during life, but the description of the necropsy leaves no doubt that one must have been present.

At the post mortem examination, on opening the abdomen a voluminous tumour was seen to occupy the left flank and hypochondrium and even to encroach upon the right of the median line It was egg shaped with its larger pole upwards. It extended from the sixth rib to the anterior superior iliac spine and measured in its vertical and transverse diameters 25 centimetres and 20 centimetres respectively, and 65 centimetres and 50 centimetres in its circumferences. It weighed 3·490 grammes. After reflecting the peritoneum from off it the tumour was seen to be prominently embossed, having seven or eight large embossments separated by deep grooves, which gave it the appearance of the large intestine of a horse greatly distended. On the under surface of the tumour, which was similarly embossed, was seen a central depression where the renal vessels and ureter entered. On laying open one of the largest of the pouches on the inner aspect of the tumour a large quantity of soft clot, besides two litres of a turbid red fluid like the lees of wine, were removed, and then was seen the irregular gaping orifice, of the size of a chicken-quill, of a branch of the renal artery. The margins of this orifice were indurated and blackened by blood which had been effused into the tissues. The cavity of the pouch was lined with a whitish flocculent membrane and had the structure of mucous membrane. There were seven other similar cavities of large size with similar contents isolated from one another, but each communicating by one or two openings as large as goose-quills with the renal pelvis. The renal pelvis itself was not dilated and was of normal appearance, but contained a calculus of the size of a bean, irregular, and black on its surface, and adherent to the mucous membrane. The calculus consisted of organised material surrounded by a shell of oxalate of lime. Six other small oxalate of lime calculi and some cretaceous material were also found in the walls of this loculated sac. A cyst of the size of a hen's egg inclosing pus mixed with blood had no communication with the other cavities. The walls of the tumour were one centimetre thick, tough, and composed of fibrous tissue, with, in some places, a soft reddish tissue which was proved to be renal parenchyma. The ureter was obstructed by blood-clot, but otherwise was normal. The urinary bladder contained 250 grammes of bloody urine, but its mucous lining was natural. The left lung was crowded upwards and the heart occupied a horizontal position. The rest of the organs were natural.

[10] Rouppe (D. Ludovico): "Nova Acta Physicho-Medica," tome iv., p 67, 1770.

[11] Traité des Maladies des Reins, vol. i., p. 250.

[12] Gazette des Hôpitaux, 1849, p. 148

Mounier thought that the calculi were formed subsequently to the rupture of the branch of the renal artery and to the dilatation of the cavity of the kidney, and gives plausible reasons for this opinion. It is not at all improbable, however, that the calculi pre-existed the injury and that the sacculation of the kidney was due to the calculus found in the renal pelvis. If this were so the blood from the ruptured renal artery found a sac ready for its reception. The case recorded by Danyau in which a large false aneurysm within the cavity of the kidney (hæmato-nephrosis) was formed in less than two months gives support to the opinion that a false aneurysm of the size and character which Mounier describes could be formed in 41 days without there being a pre-existing state of dilatation of the kidney.

CASE 6.—Mr. John Murray tells me of a case of traumatic false aneurysm of the renal artery which he saw when a student at the City Hospital in Dublin. There was a large tumour in the flank extending into the iliac fossa. It occurred in a man about 50 years of age, but was not diagnosed during life. A post-mortem examination disclosed a large mass of blood-clot and a rupture of the renal artery. The case has not been published.

ANEURYSM OF THE RENAL ARTERY NOT OF TRAUMATIC ORIGIN.

There are on record a few cases of true, and at least three of false, aneurysm which do not owe their origin to any injury so far as could be ascertained.

CASE 1.—Leudet[13] recorded a case of aneurysm of the right renal artery found on post-mortem examination of the body of a woman, aged 62 years, who died from nephritis, having suffered from albuminuria for two years and dyspnœa, cough, and general œdema for two months before death. The right kidney was less than half the size of the left, and just beyond the bifurcation of the right renal artery on the lower and smaller of the two branches into which it divided there was an aneurysm of the size of a haricot bean filled with rather soft yellowish material and communicating with the artery by an opening of almost capillary fineness. The walls of several of the arteries of this woman were calcareous. Leudet was of opinion that this little aneurysm was formed primarily in the walls of the vessel and opened subsequently into its lumen. He gives in the same journal a case of a woman, aged 70 years, who had two aneurysms on separate branches of the splenic artery. Each of them communicated with the lumen of the arterial branch on which it was situated and on one of these branches there was another small tumour of the size of a lentil inclosed in the substance of the arterial walls and projecting the outer surface of the vessel. Leudet remarks: "These aneurysms would seem, as regards their pathology, to be due to the mechanism first pointed out by Corvisart, then by Guthrie, and finally by Bérard—namely, that they are developed primarily in the thickness of the wall of the artery."

CASE 2.—Danner[14] describes an aneurysm of the size of a hazel-nut at the point of bifurcation of the right renal artery of a gouty man, aged 66 years, who had passed many uric acid and phosphate of lime calculi and who for five years before death suffered from dyspnœa, palpitations, and pulmonary congestion and who died suddenly in an attack of dyspnœa. The contents of the sac were of a blackish colour and rather adherent. The aorta, splenic and basilar arteries, and the arteries of the right kidney were calcareous and the heart was enormously hypertrophied. The right kidney was atrophied and cystic. The left kidney contained a calculus and much calculous débris.

In the Museum of St. Bartholomew's Hospital (Catalogue, vol. i., 1882, No. 1536) there is a specimen of a small aneurysm of a renal artery. The wall of the sac and of the adjacent part of the artery are thick and calcareous.

CASE 3.—Oestreich[15] reported a very interesting case of an aneurysm of the right renal artery of the size of an apple. It gave rise to no symptoms during life, developed between the kidney, suprarenal capsule, and the aorta, extended upwards behind the liver, and was almost completely filled with clot. Whether it arose within or outside the kidney is uncertain. It was discovered at the post-mortem examination of a young man who died from multiple embolisms and malignant endocarditis.

CASE 4.—Armstrong[16] published a case which he considered to be unique—viz., an aneurysm of an interlobular branch of the right renal artery. It was found after death in a man, aged 50 years, who was admitted into hospital on May 20th, 1879, with a tumour diagnosed to be of the right kidney, and who died comatose the same evening. At the post mortem examination there was chronic nephritis of the left kidney. The right kidney was apparently greatly enlarged, its capsule was adherent to the peritoneum and intestines, and there were other evidences of a circumscribed peritonitis; this enlargement was really due to a black blood-clot weighing 30 ounces beneath the capsule and surrounding the kidney itself. The renal capsule was ruptured and blood had escaped through the rupture into the peritoneal cavity. There was circumscribed peritonitis over the right kidney. In the external border of the kidney between the renal tubules was a small spherical cavity about one millimetre in diameter filled with well-organised fibrinous clot. This was the source of the hæmorrhage; and from the character of its contents and its shape Armstrong regarded it as an aneurysm. The etiology of the disease he considered to be alcohol, of which the state of other organs showed evidence.

CASE 5.—Dourlin[17] published a description of an aneurysmal tumour of the left renal artery in a man, aged 52 years, which occupied the whole of the left hypochondrium and left flank. There was no history of any injury. For two months before coming under the observation of Dourlin he had felt a considerable and disabling discomfort in the left hypochondrium and was unable to walk without suffering from time to time sudden and forcible retractions of the left testicle, accompanied by pain, which compelled him to cry out. In addition to the tumour the abdomen seemed to be tense and its walls slightly œdematous. The connexions of the tumour could not be satisfactorily made out; but the tumour increased in size and the patient suffered from time to time insupportable pains in the abdomen, the urine diminished in quantity, micturition became difficult, and vomiting and frequent attacks of months from the beginning of the symptoms. On post-mortem examination the tumour was found to be behind the peritoneum adherent by its upper end to the spleen, which was pushed upwards under the diaphragm, whilst its lower end extended into the iliac fossa. It was ovoid in form, contained about three pounds of blood, and on section proved to be a greatly loculated sac with no trace of parenchyma of kidney remaining. It communicated with the renal artery, which was dilated into an aneurysmal sac commencing immediately after its orifice from the aorta. The renal vein preserved its natural size and direction and its branches passed into the different partitions of the tumour.

[17] Journal de Chirurgie et de Médecine, Vendémiaire an. xii. (October, 1803), tome vii., p. 252.

CASE 6.—Gossett[18] related before the Medical Society of London (Nov. 30th, 1829) the case of a woman, aged 43 years, who shortly after an attack of so called rheumatic fever began to complain of severe pain in the loins and extreme tenderness over the left kidney. She died from hæmorrhage caused by the bursting of an aneurysm of the left renal artery into the renal pelvis. There had been profuse arterial hæmorrhage with dysuria and frequent attempts at micturition during life, and five days before her death she had been actually at the point of dying from loss of blood. At the post-mortem examination there were about 18 ounces of coagulum in the urinary bladder. The other viscera were healthy. No description of the aneurysm is given, but from a careful perusal of the case it is clear that no abdominal swelling was detected during life.

CASE 7.—W. W. Keen[19] has quite recently published and illustrated a very complete account of a large false aneurysm of a branch of the right renal artery which occurred in an unmarried lady, aged 45 years, who had no recollection of ever having had an injury. The interest of this case is enhanced by the fact that, like the traumatic aneurysms reported by Hochenegg and Hahn, it was successfully removed by operation. The clinical symptoms were a tumour in the right side of the *abdomen which filled the entire space between the border* of the ribs and the iliac crest, and extended from the right flank to about five centimetres on the left of the middle line. It was tense, firm, not tender, not nodulated, but apparently cystic at the inner part. The right kidney had been known to be moveable and slightly enlarged for five years, and for this length of time the patient had experienced a sense of discomfort [illegible] she had thought to [illegible] these years she had [illegible] chilliness and fever followed by nausea without vomiting. The temperature in one of the attacks reached 105° F. One attack had lasted for 10 days and another about five weeks. The urine contained neither sugar, blood, casts, crystals, albumin, nor tubercle bacilli. The diagnosis lay between hydro nephrosis and a renal new growth. Keen removed the tumour with the kidney across the abdomen (transperitoneally) through an incision 17 centimetres long over the front of the tumour. The pedicle was so broad that it had to be secured in seven different sections, the arteries being numerous and large and the veins enormously distended. The tumour was readily isolated as soon as the outer layer of the meso-colon was torn through. The operation lasted less than 30 minutes but was attended by very profound shock. The patient made a rapid recovery and left the home on the nineteenth day after the operation. After removal the tumour was found to consist of a large central mass of coagulum and a capsule. The capsule was continuous with the capsule of the kidney. The larger part of the tumour was formed of laminated blood-clot of different ages. The outer surface of the clot was recent and soft, whilst the central part consisted of older and almost completely decolourised fibrin. The renal artery and its branches ran over the wall of the sac and the lower branch of the renal artery opened into the sac. The sac did not communicate with the renal pelvis. The kidney tissue showed advanced chronic inflammatory changes and near the hilum there were a number of small renal cysts. The walls, especially the intima of the blood-vessels throughout the kidney, were of extraordinary thickness. Keen gives an illustration showing the tumour and kidney.

Although the cases I have here collected are the only instances of aneurysm of the renal artery or its branches with which I am acquainted, it is probable that many others tions or, if detected, have remained unrecorded. Now that attention is drawn to their occurrence there will, I anticipate, be other examples forthcoming in the near future.

As a result of injury [illegible] sacciform or diffused type, is of [illegible] If of the sacciform type it woul[illegible] associated with some other injur[illegible]elvis which gives rise to hæmaturia or to a large tumour consisting of blood and urine; or the sacciform aneurysm after a time ruptures and a false aneurysm is formed.

A false aneurysm, whether caused by the rupture of a sacciform aneurysm or by the direct rupture of the walls of the artery, gives rise to a tumour of great clinical interest, puzzling to diagnose, difficult and dangerous to treat, and hitherto, if not operated upon, invariably fatal to the individual afflicted.

The knowledge that an aneurysmal tumour occasionally may be a late and not an immediate consequence of injury; that it may be caused by an accident which either slightly or extensively damages the kidney; that it often ultimately leads to absolute destruction by atrophy or inflammation of the whole or a considerable part of the organ; and finally that there is great risk attached to operative treatment and certain death if such treatment is not adopted,—such knowledge ought to be an additional inducement to surgeons, if other conditions do not contra-indicate the operation, to explore early every kidney which is seriously damaged by an accident.

ETIOLOGY.

Of the 19 cases of renal aneurysm which I have collected (the case of Titius and the specimen which is in St. Bartholomew's Hospital Museum with the others make 21 cases, but they are not analysed with them because no particulars are given) 12 were traumatic and seven spontaneous. Of the traumatic cases two were sacciform when discovered after death and nine were false and one doubtful. Of the nine *false aneurysms two occurred from the bursting of a* sacciform aneurysm; one followed after a time from the yielding of a thrombus in the ruptured artery, without having been preceded by a sacciform aneurysm; five were the immediate consequence of rupture of the artery; and in one (Daniel Nebel's) the nature of the aneurysm is not described. Of the seven spontaneous aneurysms three were sacciform; one of these was of the size of an apple, and two are described as being of the size of a haricot bean and of a hazel nut respectively. One was a false aneurysm in the form of a true hæmato-nephrosis. In one case no description of the aneurysm is given beyond the fact that it ruptured into the renal pelvis. The sixth was probably sacciform originally but ruptured and became a false aneurysm, forming an intracapsular tumour surrounding the kidney. The seventh seems to have been a false aneurysm from the beginning.

Sex.—Of the 12 traumatic cases ten were in men and two were in women. In the case of one of the women there might be some doubt as to whether the sacciform aneurysm which subsequently ruptured was really of traumatic origin because, though she had a fall on a staircase, she had apoplexy from a hæmorrhage into the left thalamus and was the subject of endarteritis, her aorta and other arteries being affected. The branches of the renal artery next the clot were markedly dilated and tortuous. Of the seven spontaneous aneurysms four were in males and three were in females.

Age.—Of the traumatic cases the age is stated in ten. One was 15 years, one 19 years, one 21 years, one 25 years, one 36 years, another 30 years, and four were between the ages of 49 and 51 years. Of those whose ages are not given both were men in active life. One is described as a "young boatman"; the other as a "doctor" whose aneurysm resulted from a fall from a horse four years before his death. Of the spontaneous cases the ages of six are stated; they were all over 40 years; the youngest was 43 years and the oldest was 66 years. The seventh was described as "a young man."

Nature of injury or disease.—Of the traumatic cases one patient was thrown out of a cart; another was struck by the buffer of an engine; a third was thrown from a horse; two fell from a height, striking the loin of the side of the injured kidney; one slipped and struck his loin on the gunwale of his boat; one fell against a counter and contused his side; one fell against a box; another slipped and fell against the edge of a low wall; one was run over by a handcart; and two fell against steps or a staircase. Of the spontaneous cases malignant endocarditis with multiple embolisms was present in one case; calcareous degeneration of the coats of the arteries was present in two others. Another died from nephritis; the fifth died comatose with destruction of one kidney from the aneurysm and chronic nephritis of the opposite kidney. In the sixth the patient had what must have been erroneously called an attack of "rheumatic fever," for it passed off in five days. It seems probable that an embolism or a thrombus led to the development of the aneurysm. In the seventh case there was absolutely no assignable cause. Leudet, following Corvisart, Guthrie, and Bérard, thought the small aneurysms were developed in the substance of the wall of the vessel and subsequently opened into the lumen of the artery.

[19] Philadelphia Medical Journal, May 5th, 1900, p. 1032.

PATHOLOGICAL CONSEQUENCES.

As long as a sacciform aneurysm remains unruptured it seems not to produce any distinct changes in the kidney or part around. If situated within the kidney capsule the little tumour may press aside and more or less flatten some of the tubules, but without destroying them, as in Armstrong's case. If a sacciform aneurysm bursts into the renal pelvis profuse hæmorrhage is the result; the bladder may become distended with blood and blood-clot, and blood may flow away from the urethra, as in Gossett's and Oestreich's cases. The patient thus dies from sheer loss of blood, or from this cause combined with the pain and other effects of blood-clots distending, and decomposing within, the bladder.

When a false aneurysm is formed, whether as the effect of injury or disease and whether indirectly by the rupture of a sacciform aneurysm or directly by the giving way of the artery matters not, then serious damage is generally done to the kidney, and extensive pressure changes and displacements are wrought in the surrounding tissues and organs. The blood may distend the pelvis and calyces, and, producing complete absorption of the renal parenchyma, create a true hæmato-nephrosis; or it may be extravasated entirely within the capsule, between it and the renal parenchyma; or partly within the renal capsule and partly into the perinephric tissue; or it may be entirely outside the renal capsule completely or partially surrounding it. The kidney may have undergone complete or partial atrophy; or the kidney, if any remains of it, may be spread out in the wall of the sac as it was in the case under my own care in which the kidney had almost, and its adrenal had completely, disappeared.

When part of the kidney has been flattened out or absorbed the rest of the organ may appear to be covered by the same capsule. Even when the aneurysm has been stated to be entirely separate from the kidney it is yet described as being in the same capsule (Hahn). This condition of the capsule is, I have no doubt, in some cases only apparent, not real. The matting together of the sac of the aneurysm and the structures adjacent becomes so intimate and firm that it is impossible to say where renal capsule ends and sac begins. It is the same with the capsule of an adrenal tumour, as I pointed out in an article on Tumours of the Adrenal published in another journal some months ago.[20]

The blood may filter along the course of the vessels and thus get within the capsule of the kidney and thence break into the calyces. If the blood is really extravasated within the renal capsule it may either break down and disintegrate the parenchyma and rupture the capsule or spread between the parenchyma and the capsule (Armstrong's and Rouppe's cases).

If the capsule is stripped up from the parenchyma the latter may be undamaged except that its outer surface is slightly roughened or eroded; but the capsule may be greatly distended and even ruptured, and thus blood may escape into the peritoneal cavity (Armstrong's case) as well as into the retro-peritoneal tissue.

The tumour may displace and become extensively adherent to neighbouring structures The colon is commonly displaced towards the median line, the liver and spleen are pressed upwards, and the diaphragm may be raised upwards. Some of the adhesions of the sac wall may be loose and easily separated, others may be so dense and strong that they are absolutely inseparable—as was the case between the sac and the diaphragm and the sac and some parts of the peritoneum in my patient

The contents of the sac are, for the most part, blood-clot; there is sometimes only a very little fluid blood or blood serum, so that not more than a drachm or two can be drawn off when the tumour is tapped in the course of exploring it

The clot in the sac is of different ages, colour, and consistence. In some cases it has been found nearly all laminated; in others chiefly passive; in others, again, disintegrated.

When a small sacciform aneurysm and a blood tumour co-exist the source of the blood which forms the tumour is not always the vessel upon which the small sacciform aneurysm is situated. The blood may be derived from a ruptured vein or from the parenchyma (Reeves's case), neither the artery on which the aneurysm is situated nor the small aneurysm itself being lacerated. The blood may be derived from the vessel on which a small aneurysm is situated and not from the aneurysm itself (Hilton's case); when this is so two aneurysmal conditions really co-exist in connexion with the same vessel—namely, a small sacciform aneurysm and a large false aneurysm.

The perinephric tumour co-existing with the small sacciform aneurysm may be composed partly of blood and partly of urine, the blood being derived either from the aneurysm or the artery on which it is placed or from a different source altogether. The urine comes from a lacerated renal pelvis or calyx (Reeves's and Hilton's cases) or ureter. Either a spontaneous (Gossett's) or a traumatic (Oestreich's) aneurysm may burst into the renal pelvis. In Daniel Nebel's case as well as in Armstrong's death was caused by the rupture of the aneurysm into the peritoneal cavity. Both local and general peritonitis have been caused by the aneurysm, and in Hilton's case there was a slough with a perforation in the peritoneum over the tumour.

SYMPTOMS.

An unruptured sacciform aneurysm gives rise to no clinical symptoms and is only discovered at the post-mortem examination of a person who has died from some other disease or from some other effects of the same accident which caused the aneurysm.

It is possible that a small unruptured aneurysm no larger than a haricot bean may assist in producing atrophy of the kidney (Leudet's and Danner's cases), but this would be unattended with any clinical signs.

A false aneurysm, no matter how formed, whether traumatic or spontaneous, probably always causes, sooner or later, a tumour, and nearly always gives rise to hæmaturia. There are no symptoms other than these (tumour and hæmaturia) which are commonly due to the rupture of a sacciform renal aneurysm or of the wall of the renal artery itself.

Tumour.—A tumour was detected during life in 14 out of the 19 cases, and in one other it is quite certain that a tumour must have existed. The size of the tumour varies from that of a double fist to a swelling which fills half the abdominal cavity, reaching vertically from the false pelvis to the dome of the diaphragm which it pushes upwards, and laterally from the side of the flank inwards as far as or beyond the median line, bulging the loin backwards and outwards and the abdominal parietes forwards.

The date of its appearance and the rate of its growth vary according to the degree of resistance of the tissues into which the blood is effused and the extent and firmness of the coagulum which for a time may close the rent in the vessel or the aneurysmal wall. In one case (Rouppe's) which ended fatally and suddenly on the tenth day—no doubt from the rupture of the false aneurysmal sac which was formed by the capsule of the kidney—the tumour was only detected a few hours before death. When the extravasation is into the perinephric tissue it does not follow that the tumour appears earlier or grows more rapidly than when it is within the capsule or actually within the pelvis and calyces of the kidney. If the first effect of the injury is the formation of a small sacciform aneurysm, or of a rent in the vessel wall which becomes plugged by coagulum all the immediate clinical symptoms due to the accident may pass off, and the patient may be dismissed as quite well, and a longer or shorter interval may elapse before any signs at all are detected of a tumour. On the other hand, the presence of a swelling may be detected at once, or within a few days after the injury, as in Hahn's case and my own. It is possible that a small aneurysm might rupture into the renal pelvis or a calyx and cause death by hæmorrhage without giving rise to a tumour; unfortunately, in one case in which death was brought about in this way no description of the aneurysm is supplied (Gossett's). In Oestreich's case of traumatic aneurysm where hæmorrhage into the renal pelvis occurred there was a large tumour in communication with the renal pelvis.

---

[20] Brit. Med. Jour., Nov. 11th, 1899

The tumour, on bedside examination, is generally neither irregular nor nodulated on the surface, and no case is related where the kidney formed a projection upon the tumour, as it does sometimes in perinephric extravasations and in some tumours of the kidney or adrenal. The tumour is but slightly moveable, if it is not actually fixed; it rarely if ever moves with ordinary respiration or by change of posture, though in several of the cases there has been some antero-posterior mobility on bimanual examination (*ballottement*). The abdominal parietes may be tightly stretched over the tumour, but have no appearance of being adherent to it or infiltrated by it. No enlarged veins in the parietes, no recently developed varicocele such as is seen in some cases of new growth of the kidney and adrenal, no œdema (except a slight degree in Dourlin's case), and no marked redness have been noted.

Pain.—The tumour is not generally tender on pressure or the seat of acute pain. On the other hand, it may give rise [illegible] Dourlin's and other cases. If it [illegible] may cause some discomfort or a [illegible] pain in the loin occurred for three months before a tumour was detected; in another there was severe pain in the sacral region from time to time, especially on sitting. Pain and tenderness may exist if localised peritonitis is present. In Gossett's case the tenderness over the kidney of the affected side was so great that the patient could scarcely bear the pressure of her clothes. In most of the cases there has been severe pain immediately after the injury which caused the aneurysm. In Dourlin's patient retraction of the testes of the same side was a striking symptom.

Hæmaturia.—This is a very common symptom and the next most important to tumour. Indeed, it may be the most important symptom and may possibly be fatal before any tumour has been formed. More frequently than tumour hæmaturia is the earliest symptom and may precede tumour by many months or even a year or two. It may commence immediately and go on for months after the injury or to the end of life; or beginning at the outset of the case it may cease after a day or two and remain absent for months; in my case it commenced immediately after the injury, continued for five months, then ceased, and did not re-appear, though the patient survived for four and a half years longer. It may not commence, however, till long after a tumour has been known to exist, as in Keen's case of spontaneous false aneurysm, and then it was but a trace, and only noticed on one occasion. A small sacciform aneurysm may rupture immediately into the renal pelvis or a false aneurysm may open by ulceration into it, and then the hæmorrhage may be profuse and fatal. There may be hæmaturia, without any direct communication between the renal pelvis and the aneurysm, owing to the extravasated blood burrowing inwards from the hilum and breaking into a calyx or disintegrating the parenchyma. Hæmaturia may be coincidental and not directly connected with the aneurysm, but may arise from other injuries to the kidney, as probably was the case in Reeves's patient.

When the hæmorrhage is very profuse the blood may flow away freely through the bladder and out of the external urethral meatus; or long clots may be extruded from the urethra. If this happens in the female it may be mistaken for uterine hæmorrhage or bleeding from the genitalia (as in Gossett's and Oestreich's cases) unless a careful examination is made.

Pulsation.—This symptom, so characteristic of most other aneurysms, is remarkable by its absence in renal aneurysm. In two cases (Hahn's and my own) it was suspected to exist and in each of these it was very indistinct if really present; in neither instance could it be made out on most careful palpation of the tumour just before and during the operation. In one case (Daniel Nebel's) pulsation was detected and the case diagnosed as an aneurysm. In Gruber's case it is stated there was no pulsation, neither were there any auscultation signs. As Keen has remarked: "The chief reason why the diagnosis has not been made is that the artery is relatively small and the sac very large, hence the impulse of the blood is not sufficient to distend the large sac and produce pulsation."

Auscultation.—Observation on this point seems only to have been made in one case beside my own and in that case no bruit was detected. In my patient's tumour there was no thrill, but there was a loud systolic bruit over the tumour, best heard in front, but which did not extend along the vessels towards the groins.

The urine.—Except for the presence of blood, or of a little albumin in the intervals between the attacks of hæmaturia, the urine is normal. If some independent disease affects the kidney, or if pyelitis follows a laceration of the kidney caused by the same accident which produced the aneurysm (Reeves's case), then albumin, renal casts, or pus may be passed. Dysuria and frequent micturition have been noted when blood-clots were passing or when the bladder was filled with blood or decomposing blood-clot, and also in Dourlin's case in which hæmaturia is not mentioned as having occurred.

The general symptoms.—These are only such as would be expected from the loss of blood and the pressure effects of the tumour. Loss of strength, loss of flesh, pallor, nausea with or without vomiting, and gastro-intestinal disturbances, such as loss of appetite, indigestion, flatulent distension, and constipation, have been complained of by some, but by no means all, of the patients. Rigors, fever, and rapid emaciation do not occur unless, indeed, the so-called "bilious attacks" with high temperature described in Keen's case can be ascribed to the aneurysm, which is most improbable.

DIAGNOSIS.

As a small sacciform aneurysm, so far as is at present known, causes no symptoms whatever, the question of diagnosis in such cases does not arise. I should not be surprised, however, as time goes on if the symptoms attributed to renal calculus prove on exploration to be in very exceptional cases due to a small aneurysm of the renal trunk or one of its branches.

It is the tumour caused by a false aneurysm which is so difficult to diagnose. The affections with which it is most apt to be confused are renal and adrenal new growths, true and false hydro- or hæmato-nephrosis, and ruptured kidney. The history of an injury is but of little help when the tumour occurs a few months after a fall unless there has been continuous hæmaturia or frequent recurrences of hæmaturia ever since the accident, because malignant growths are also apt to follow injury. Neither is hæmorrhage, no matter how profuse or how bright the blood which flows, in favour of aneurysm as distinct from renal new growths, especially new growths of the renal pelvis. Nor does the rate of increase of the swelling render much assistance in distinguishing the one from the other. Pain and tenderness, rapid emaciation, large veins on the abdominal parietes, varicocele recently developed, and the presence or suspicion of a malignant growth in some *other part or organ would point to malignant* renal, or adrenal, tumour. Hydro-nephrosis is usually more elastic if not fluctuating, often intermits contemporaneously with marked variations in the quantity of urine passed, is in many cases very painful or even agonising at the times of great distension of the kidneys, is seldom if ever accompanied by hæmaturia, and is never attended by profuse hæmorrhage, and more frequently than not is unassociated with any history of injury. Hæmato-nephrosis develops quickly or even suddenly, often without violence, gives rise to intense pain and much constitutional disturbance, and has most likely been preceded by the symptoms of some other renal affection, such as tumour, calculus, or ureteral obstruction; but the true hæmato-nephrosis, it should be remembered, may be really a false aneurysm either of traumatic or spontaneous origin. In false hydro- or hydro-hæmato-nephrosis following ruptured kidney the tumour is generally developed very rapidly, is attended with great pain, and if the renal cavity is opened there is a diminished amount of urine passed naturally; the urine, at a later stage, will probably contain pus if the patient survives. There is, too, in these cases generally much more shock at the time of the injury and a great deal of constitutional disturbance, with, in some cases, rigors, high temperature, or hectic when the condition has advanced.

It must be borne in mind, however, that perinephric extravasation due to injured kidney or ureter is sometimes delayed for weeks after the accident, and, on the other hand, a hæmatoma from a ruptured renal artery (that is, a false aneurysm) may commence to form from the moment of the accident. In the absence of pulsation in the tumour there handcart; and two fell against steps or a staircase. Of the spontaneous cases malignant endocarditis with multiple embolisms was present in one case; calcareous degeneration of the coats of the arteries was present in two others. Another died from nephritis; the fifth died comatose with destruction of one kidney from the aneurysm and chronic nephritis of the opposite kidney. In the sixth the patient had what must have been erroneously called an attack of "rheumatic fever," for it passed off in five days. It seems probable that an embolism or a thrombus led to the development of the aneurysm. In the seventh case there was absolutely no assignable cause Leudet, following Corvisart, Guthrie, and Bérard, thought the small aneurysms were developed in the substance of the wall of the vessel and subsequently opened into the lumen of the artery.

PATHOLOGICAL CONSEQUENCES.

As long as a sacciform aneurysm remains unruptured it seems not to produce any distinct changes in the kidney or part around. If situated within the kidney capsule the little tumour may press aside and more or less flatten some of the tubules, but without destroying them, as in Armstrong's case. If a sacciform aneurysm bursts into the renal pelvis profuse hæmorrhage is the result; the bladder may become distended with blood and blood-clot, and blood may flow away from the urethra, as in Gossett's and Oestreich's cases. The patient thus dies from sheer loss of blood, or from this cause combined with the pain and other effects of blood-clots distending, and decomposing within, the bladder.

When a false aneurysm is formed, whether as the effect of injury or disease and whether indirectly by the rupture of a sacciform aneurysm or directly by the giving way of the artery matters not, then serious damage is generally done to the kidney, and extensive pressure changes and displacements are wrought in the surrounding tissues and organs. The blood may distend the pelvis and calyces, and, producing complete absorption of the renal parenchyma, create a true hæmato-nephrosis; or it may be extravasated entirely within the capsule, between it and the renal parenchyma; or partly within the renal capsule and partly into the perinephric tissue; or it may be entirely outside the renal capsule completely or partially surrounding it The kidney may have undergone complete or partial atrophy; or the kidney, if any remains of it, may be spread out in the wall of the sac as it was in the case under my own care in which the kidney had almost, and its adrenal had completely, disappeared.

When part of the kidney has been flattened out or absorbed the rest of the organ may appear to be covered by the same capsule. Even when the aneurysm has been stated to be entirely separate from the kidney it is yet described as being in the same capsule (Hahn). This condition of the capsule is, I have no doubt, in some cases only apparent, not real. The matting together of the sac of the aneurysm and the structures adjacent becomes so intimate and firm that it is impossible to say where renal capsule ends and sac begins. It is the same with the capsule of an adrenal tumour, as I pointed out in an article on Tumours of the Adrenal published in another journal some months ago.[20]

The blood may filter along the course of the vessels and thus get within the capsule of the kidney and thence break into the calyces. If the blood is really extravasated within the renal capsule it may either break down and disintegrate the parenchyma and rupture the capsule or spread between the parenchyma and the capsule (Armstrong's and Rouppe's cases).

If the capsule is stripped up from the parenchyma the latter may be undamaged except that its outer surface is slightly roughened or eroded; but the capsule may be greatly distended and even ruptured, and thus blood may escape into the peritoneal cavity (Armstrong's case) as well as into the retro-peritoneal tissue

The tumour may displace and become extensively adherent to neighbouring structures. The colon is commonly displaced towards the median line, the liver and spleen are pressed upwards, and the diaphragm may be raised upwards. Some of the adhesions of the sac wall may be loose and easily separated, others may be so dense and strong that they are absolutely inseparable—as was the case between the sac and the diaphragm and the sac and some parts of the peritoneum in my patient.

The contents of the sac are, for the most part, blood-clot; there is sometimes only a very little fluid blood or blood serum, so that not more than a drachm or two can be drawn off when the tumour is tapped in the course of exploring it.

The clot in the sac is of different ages, colour, and consistence. In some cases it has been found nearly all laminated; in others chiefly passive; in others, again, disintegrated.

When a small sacciform aneurysm and a blood tumour co-exist the source of the blood which forms the tumour is not always the vessel upon which the small sacciform aneurysm is situated. The blood may be derived from a ruptured vein or from the parenchyma (Reeves's case), neither the artery on which the aneurysm is situated nor the small aneurysm itself being lacerated. The blood may be derived from the vessel on which a small aneurysm is situated and not from the aneurysm itself (Hilton's case); when this is so two aneurysmal conditions really co-exist in connexion with the same vessel—namely, a small sacciform aneurysm and a large false aneurysm.

The perinephric tumour co-existing with the small sacciform aneurysm may be composed partly of blood and partly of urine, the blood being derived either from the aneurysm or the artery on which it is placed or from a different source altogether. The urine comes from a lacerated renal pelvis or calyx (Reeves's and Hilton's cases) or ureter.—Either a spontaneous (Gossett's) or a traumatic (Oestreich's) aneurysm may burst into the renal pelvis. In Daniel Nebel's case as well as in Armstrong's death was caused by the rupture of the aneurysm into the peritoneal cavity. Both local and general peritonitis have been caused by the aneurysm, and in Hilton's case there was a slough with a perforation in the peritoneum over the tumour.

SYMPTOMS.

An unruptured sacciform aneurysm gives rise to no clinical symptoms and is only discovered at the post-mortem examination of a person who has died from some other disease or from some other effects of the same accident which caused the aneurysm.

It is possible that a small unruptured aneurysm no larger than a haricot bean may assist in producing atrophy of the kidney (Leudet's and Danner's cases), but this would be unattended with any clinical signs.

A false aneurysm, no matter how formed, whether traumatic or spor[illegible] causes, sooner or later, a tumour, [illegible] rise to hæmaturia. There are no sy[illegible]ese (tumour and hæmaturia) whic[illegible] the rupture of a sacciform renal aneurysm or of the wall of the renal artery itself.

Tumour.—A tumour was detected during life in 14 out of the 19 cases, and in one other it is quite certain that a tumour must have existed. The size of the tumour varies from that of a double fist to a swelling which fills half the abdominal cavity, reaching vertically from the false pelvis to the dome of the diaphragm, which it pushes upwards, and laterally from the [illegible] of the [illegible] inwards as far as or beyond the median line, bulging the loin backwards and outwards and the abdominal parietes forwards.

The date of its appearance and the rate of its growth vary according to the degree of resistance of the tissues into which the blood is effused and the extent and firmness of the coagulum which for a time may close the rent in the vessel or the aneurysmal wall. In one case (Rouppe's) which ended fatally and suddenly on the tenth day—no doubt from the rupture of the false aneurysmal sac which was formed by the capsule of the kidney—the tumour was only detected a few hours before death. When the extravasation is into the perinephric tissue it does not follow that the tumour appears earlier or grows more rapidly than when it is within the capsule or actually within the pelvis and calyces of the kidney. If the first effect of the injury is the formation of a small sacciform aneurysm, or of a rent in the vessel wall which becomes plugged by coagulum all the immediate clinical symptoms due to the accident may pass off, and the patient may be dismissed as quite well, and a longer or shorter interval may elapse before any signs at all are detected of a tumour. The urine.—Except for the presence of blood, *or of a little albumin in the intervals between* the attacks of hæmaturia, the urine is [illegible] disease affects the kidney [illegible] of the kidney caused by [illegible] the aneurysm (Reeves's case), then *albumin, renal casts,* or pus may be passed. Dysuria and frequent micturition have been noted when blood-clots were passing or when the bladder was filled with blood or decomposing blood-clot, and also in Dourlin's case in which hæmaturia is not *mentioned as having occurred.*

The general symptoms [illegible] expected from the loss [illegible] the tumour. Loss of st [illegible] with or without vomiting [illegible] such as loss of appetite, [illegible] constipation, have been complained of by some, but by *no* means all, of the patients. Rigors, fever, and rapid emaciation do not occur unless, indeed, the so-called "bilious attacks" with high temperature described in Keen's case can be ascribed to the aneurysm, which is most improbable.

DIAGNOSIS.

As a small sacciform aneurysm, so far as is at present known, causes no symptoms whatever, the question of diagnosis in such cases does not arise. I should not be surprised, however, as time goes on if the symptoms attributed to renal calculus prove on exploration to be in *very exceptional cases due to a small aneurysm of the* renal trunk or one of its branches.

It is the tumour caused by a false aneurysm which is so difficult to diagnose. The affections with which it is most apt to be confused are renal and adrenal new growths, true and false hydro- or hæmato nephrosis, and ruptured kidney. The history of an injury is but of little help *when the tumour occurs a few months after a fall* unless there has been continuous hæmaturia or frequent recurrences of hæmaturia ever since the accident, because malignant growths are also apt to follow injury. Neither is hæmorrhage, no matter how profuse or how bright the blood which flows, in favour of aneurysm as distinct from renal new growths, especially new growths of the renal pelvis. *Nor* does the rate of increase of the swelling render much assistance in distinguishing the one from the other. Pain and tenderness, rapid emaciation, large veins on the abdominal parietes, varicocele recently developed, and the presence or suspicion of a malignant growth in some other part or organ would point to malignant renal, or adrenal, tumour. Hydro-nephrosis is usually more elastic if not fluctuating, often intermits contemporaneously with marked variations in the quantity of urine passed, is in many cases very *painful or even agonising* at the times of great distension of the kidneys, is seldom if ever accompanied by hæmaturia, and is never attended by profuse hæmorrhage, and more frequently than not is unassociated with any history of injury.[1] Hæmato-nephrosis develops quickly or even suddenly, often without violence, gives rise to intense pain and much constitutional disturbance, and has most likely been preceded by the symptoms of some other renal affection, such as tumour, calculus, or ureteral obstruction; but the true hæmato-*nephrosis*, it should be remembered, may be really a false aneurysm either of traumatic or spontaneous origin. In false hydro- or hydro-hæmato-nephrosis following ruptured kidney the tumour is generally developed very rapidly, is attended with great pain, and if the *renal cavity is opened* there is a diminished amount of urine passed naturally; the urine, at a later stage, will probably contain pus if the patient survives. There is, too, in these cases generally much more shock at the time of the injury and a great deal of constitutional disturbance, with, in some cases, rigors, high temperature, or hectic when the condition has advanced.

It must be borne in mind, however, that perinephric extravasation due to injured kidney or ureter is sometimes delayed for weeks after the accident, and, on the other hand, a hæmatoma from a ruptured renal artery (that is, a false aneurysm) may commence to form from the moment of the accident. In the absence of pulsation in the tumour there is absolutely no way that I know of, except by an exploratory operation, to distinguish a simple hæmatoma or a true hæmato-nephrosis due to a ruptured vein or ruptured renal parenchyma from a hæmatoma or a hæmato-nephrosis due to a ruptured artery—i.e., a primary false aneurysm. If some weeks or months after an injury, and perhaps after a period of apparent health, a tumour develops having the characters above described, a suspicion of renal aneurysm ought to be aroused and the treatment ought to be directed accordingly.

PROGNOSIS.

The prognosis in false aneurysm is most unfavourable; all the cases hitherto reported which have not been operated upon have died. Only four have been operated upon and three out of the four recovered; the other died. The three successful cases are Albert's, Hahn's, and Keen's. The two former were of traumatic origin. Keen's was a spontaneous false aneurysm. In the unsuccessful case the operation was rapidly followed by a fatal result. This may possibly have been in part attributable to the nature of the operation employed, but the enormous size and the firm adhesions and the other conditions of the tumour would, I think, have made any operation unsuccessful. The descriptions of the operations show how very severe they were and with what great risks they were attended.

All the patients with aneurysmal tumours not operated upon died from their aneurysms. Another case (Reeves's) where a small aneurysm was associated with a tumour caused by perinephric extravasation of blood and urine from laceration of the kidney was also fatal, but not from the aneurysm. One patient in whom no tumour was present died from hæmorrhage due to the rupture of the aneurysm into the renal pelvis. In the remaining three out of the total of 19 cases the aneurysms were quite small and were found in persons who died from causes other than the aneurysm.

The causes of death of the patients not operated upon have been profuse hæmorrhage from rupture into the renal pelvis (three cases), [illegible]ritoneal cavity, hæmorrhage into th[illegible] from rupture of the false sac, ar[illegible] case in which the patient died af[illegible] due to shock and loss of blood, [illegible] been operated upon his life could not have been much prolonged, as the contents of the sac were beginning to break down. Some of the aneurysms have existed a long time before death occurred or before the operation was performed. In Keen's case and my own five years had elapsed; in the case of the medical man who fell from his horse four years; and in Hochenegg's case two years. In Gruber's case the patient lived only ten months after the accident and but two months after the detection of the tumour. The most rapidly fatal cases were those in which the aneurysm burst into the renal pelvis; in one of them—a case of spontaneous aneurysm—the first symptoms referable to the kidney were pain and tenderness, and death from hæmorrhage followed on the ninth day.

In another, a case of traumatic aneurysm, the injury happened three months before death, but the tumour was detected only three days before: hæmaturia commenced about a month after the fall, rapidly became worse, then excessive, and continued to the end of life. In Hahn's case two months elapsed after the accident before a tumour was found and the operation was performed a week later; there seem to have been no hæmaturia and no albuminuria throughout and their absence no doubt was a reason why the tumour was diagnosed as being hydro-nephrosis.

In Rouppe's case a tumour suddenly developed with violent pain, faintness, and thirst nine days after the accident, and the patient was dead in 10 hours. Hæmaturia, in this case at first considerable, had ceased some days before the tumour appeared. In Mounier's case the accident occurred on Jan. 20th and death followed on Feb. 14th. In Danyau's case the accident occurred in the early part of October and death took place on Nov. 26th.

TREATMENT.

When a tumour due to a renal aneurysm exists the only prospect of saving life is by nephrectomy and the removal of the whole or the greater part of the aneurysmal swelling. The operation will in most instances have to be commenced as an exploratory proceeding, for though the surgeon may suspect an aneurysm he cannot diagnose it from a hæmatoma due to a ruptured vein or lacerated kidney unless there be pulsation, which, as we have seen, there rarely, if ever, is. In other cases the tumour will be mistaken for a new growth or a hydro-nephrosis. The course to pursue is to commence by making an oblique incision in the loin. As soon, however, as the nature of the tumour is ascertained either the lumbar incision should be considerably prolonged forwards and the renal pedicle reached and cleared by reflecting the peritoneum inwards from off the tumour; or, what is even better if the tumour is very large, the patient should be turned over and a transperitoneal operation performed by opening the abdomen in front along the linea semilunaris of the same side as the tumour, then the peritoneum should be divided along the outer side of the colon, and reflected inwards thereby the pedicle of the kidney is cleared. The whole pedicle should be secured, or at any rate the renal artery should be ligatured before attempting to empty or remove the sac. The nature of the tumour will not at once be revealed on exposing the sac from the loin, but it soon will be if a small incision is made through the sac wall and the contents are found to consist of laminated blood-clot. There may be very little fluid in the sac, and that of a thin pinkish or pinkish-yellow or dirty light brown colour, which will not at all assist the diagnosis, so that a mere puncture of the sac-wall with a trocar and cannula is not sufficient. If, when the sac is incised and a little of its solid contents are removed for examination hæmorrhage occurs, the small opening should be immediately plugged with gauze and the pedicle secured in the manner just described. It is undesirable and dangerous to proceed to remove much of the clot. All that is necessary or safe to be done is to make a small incision through the sac wall sufficient to remove enough of the contents for diagnostic purposes, and as soon as the laminated nature of the clot is detected to cease from further disturbing the sac contents till the vessels of the pedicle are securely tied. It was by not following this course (but by adopting the plan which John Bell employed and so graphically described in a case of gluteal aneurysm and which I once successfully employed in a large aneurysm near the bifurcation of the carotid) that the alarming character and some of the difficulty of the operation in my case of renal aneurysm were due, and I thus specially refer to it as a warning to others. It is the first and only case of renal aneurysm I have had to operate upon, and should it fall to my lot to operate again in a similar case I shall do so by the method and with the precautions I now inculcate. The plan adopted by Albert was a nearly transverse incision from a point a little inside the mammary line outwards for about 20 centimetres and passing about two fingers' breadth below the right arch of the ribs posteriorly. The peritoneum was not opened but was reflected inwards so as to expose the tumour in the hinder part of the wound. The patient was placed on his left side during the operation. Keen's operation was an ordinary anterior or transperitoneal one. Hahn combined the lumbar and transperitoneal methods.

The risks necessarily attending the operation are hæmorrhage and shock. Albert met with severe hæmorrhage from laceration of the renal artery on separating the loose adhesions. This was arrested by iodoform gauze packing and a pair of hæmostatic forceps which were left in place for five days. Hahn on puncturing the tumour through a lumbar incision drew blood, and on attempting to loosen the inferior pole of the tumour a sudden profuse hæmorrhage occurred which he checked by packing the wound. He then proceeded by the anterior incision. In Keen's case, which was commenced and completed through an anterior incision, the patient, in spite of the injection of the saline solution into the veins of the arm, and also of the fact that not over four ounces of blood were lost, was "very profoundly shocked." The pedicle in Keen's case also gave some trouble, being "so broad that it had to be secured in seven different sections, the arteries being numerous and large and the veins especially enormously distended." Another risk is due to the adhesions which may unite the wall of the aneurysm with the peritoneum and bowel, the diaphragm, solid viscera, and prævertebral vessels. If the adhesions are tough and firm, as they were in my patient, it may be impossible to remove the whole of the sac wall. When such tough connexions are present entire separation of the cyst should not be attempted. As much of its wall as possible should be removed and the rest left and drained.

Cavendish-square, W.

A CASE OF ACUTE ALBUMINURIA (ACUTE RENAL CONGESTION) WITH URÆMIA; RECOVERY.

BY F C EVILL, M R C S ENG; L R C P LOND

WITH TWO SIMILAR CASES AND COMMENTS

BY SAMUEL WEST, M D. OXON., F.R.C.P LOND

ON Jan 28th, 1900, I was called to see a man, aged 36 years, who was suffering from insomnia, dyspnœa, and acute headache. As to his family history, his father had died from Bright's disease at the age of 57 years; other members of his family were living and were in good health The previous history of the patient showed that he had had no serious illness During the last nine years he had been sole manager of a large business entailing much and constant mental strain; and coupled with this was the fact that for the whole of this period he had never had a reasonable holiday Three weeks before I saw him he had what he thought was influenza (for which he had no medical advice) and he had not since recovered his usual health The patient was naturally a man of strong physique and he thought nothing of taking a 50-mile walk at a stretch for "exercise" On Jan 28th he complained of intense headache, inability to sleep, and a choking sensation in his throat The respirations were 24, with constant coughing, straining, and retching His face, neck, hands, and wrists were puffy. There was no ascites or œdema of the legs or of the body The pulse was 84 and small and the arteries were soft and compressible The lungs were clear; there were no adventitious sounds and no cardiac lesion The urine was smoky, blood and casts were present, and about one third of albumin was apparent on boiling it The patient was ordered bed, warmth, woollen garments, and a milk diet, and a mixture containing tincture of digitalis, spirit of nitrous ether, and solution of citrate of ammonia, was prescribed On the 29th he had had a sleepless night All his symptoms were intensified The quantity of urine had amounted in 24 hours to 20 ounces More blood and one half of albumin were present The bowels opened freely with compound powder of jalap One tenth of a grain of pilocarpin was injected The skin was very dry. On the 30th
the patient h
repeated ada
dyspnœa and
so at night,
drop doses o
quantity and was solid with albumin on boiling The patient's condition was steadily growing worse in spite of counter irritation and dry cupping over the kidneys and the
injection of
a day, the
urinous odo
passed in the 24 hours At no time had the temperature risen above 99 4° F On the 2nd I was called at 3 A M and found the patient semi conscious, fighting for breath as though choking retching and straining, and throwing himself about the bed, calling out constantly from the agonising pain in his head The respirations varied between 45 and 56 and the pulse was 112, small, and irregular. I performed venesection and removed 20 ounces of blood, this moderated the pain in the head and relieved the general condition perceptibly I telegraphed to Dr Samuel West, asking him to see the patient At 8 A M, while preparing the patient for a vapour-bath, he was suddenly seized with a violent uræmic fit which lasted about 15 minutes and left him in a semi comatose condition At 10 A M Dr West saw him with me and at that time the patient had reverted to very much the same condition as that in which he had been before the fit The same treatment was continued with increased doses of diaphoretics and with dry cupping vapour baths, and pilocarpin as before A diet of milk and raw meat juice was ordered There was free purging By the evening the patient seemed easier and by midnight, some oxygen at Dr West's suggestion, having been procured, the gas was administered for 20 minutes at a time every two hours The good effect of the oxygen was most marked, the dyspnœa being relieved, the patient being quieted, and sleep being procured. On the morning of the 3rd there was a decided improvement though there was still grave cause for anxiety The same treatment was continued and from this time steady improvement resulted. There were no more convulsions, the skin began to act freely, and the kidneys recovered their functions On the 4th 24 ounces of urine were passed with less blood and albumin present Each day more urine was secreted, till from the 10th to the 15th the daily average amount was 76 ounces, the partial suppression giving place to over-secretion There were no hindrances to recovery. Pilocarpin was discontinued on Feb 8th, vapour baths on the
of adm
12th
all dyspnœa had disappeared, for the reason that the gas seemed to act as an antidote to the toxins in the blood and to do good in purifying the system long after its use was indicated simply to relieve dyspnœa By the 22nd all albumin had disappeared from the patient's urine and there has been no trace of it since After five weeks' holiday the patient returned to his ordinary occupation and ordinary habits and has since been perfectly well

The interest of the case lies in the rarity of the kind of attack and in the still greater rarity of recovery from it. The acute renal congestion was not an intercurrent attack in the course of chronic renal disease There were, and are, no signs or symptoms of granular kidney, no cardiac hypertrophy, and no changes in the retinal or other arteries. Beyond the supposed attack of influenza three weeks before there were no indications of its being a sequela or complication of any other disease, and the cause of it is veiled in obscurity At the time of the uræmic convulsions the patient's condition was most grave and Dr West agreed with me in thinking it to be almost desperate The patient's recovery must be attributed primarily to his own vigorous constitution, and I consider the most potent factors in the treatment were (1) the free venesection at the critical moment, and (2) the subsequent administration of oxygen, which latter was most efficacious in cleansing the blood from the toxins the presence of which was the exciting cause of all the grave and distressing symptoms

NOTE BY DR WEST.

This case is an extremely interesting one The attack described above was very severe and the patient passed very rapidly into a uræmic state When I saw him (a few hours after the convulsive attack) he was in a condition of great restlessness and excitability, hardly lying still for a second, rolling from side to side, throwing the clothes off, complaining constantly of headache and occasionally twitching With all that his mind was clear This excitability was greatly relieved by the inhalation of oxygen It is very remarkable that this patient lived, and still more remarkable that he should now be perfectly well and without a trace of albumin in the urine

Strange to say, about the same time I saw two similar cases in consultation, the patient in one of which died, while the other made complete recovery I saw the patient who died in consultation with Dr Clemow who has furnished me with the following notes "A gentleman, 41 years of age, who had been ailing for a few months, but without any definite symptoms, was attacked with influenza which left him still weaker Three weeks after this attack he was seized quite suddenly with severe headache and lumbar pain The temperature was raised for a day or two, reaching at its maximum 103° F Three days later he passed very little urine and on examination it was found to be nearly solid with albumin and to contain much blood and many casts. There was no œdema of the ankles or buttocks or any puffiness of the face, and none developed About the same time he had a good deal of *muco purulent discharge from the* nose, but there was no evidence of diphtheria He was treated in the usual way for acute albuminuria"

I saw him after he had been one week ill At that time he was in a similar condition to that described in the first case, being very restless, unable to sleep, with constant headache, occasional sickness, and a good deal of subjective dyspnœa for which no cause was evident Hiccough set in and became severe It added greatly to his misery and kept him from getting even snatches of sleep The urine was reduced to four or five ounces only a day Various methods of treatment were adopted but no relief was given, and the patient died a few days later, after about 14 days of illness, having at the last had a few slight fits.

The two cases described were the exact counterparts of one another, though one died and the other recovered. Both, strange to say, had had attacks of influenza two or three weeks previously and they had not taken sufficient care of themselves afterwards. I cannot assert that influenza had anything to do with the attack in either case, but the association is worth noting.

The third case I saw in consultation with Dr. Coates and Dr. Webb. It was that of a man, aged about 60 years, who had been much overworked for many months. His first symptom was sudden headache and general illness, for which no cause was obvious. Routine examination of the urine—for no special symptoms suggested renal mischief—showed the urine to be nearly solid with albumin. The night of the attack he slept hardly at all; he was constantly muttering and wandering, was very restless and was suffering intensely with general headache. He was treated on general principles. This condition lasted for three or four days and then improvement set in, both in the symptoms and in the state of the urine, and by the end of the week all albumin had disappeared from the urine and, except for debility, the patient was convalescent.

It is a remarkable experience that three cases of this kind should come under my observation in about as many weeks, for they must be extremely rare. They were all instances of most acute albuminuria, with blood, casts, and great diminution in the amount of urine, in the fatal case amounting almost to suppression (there were from four to five ounces only in the 24 hours), and in the two cases of recovery amounting to from 10 ounces to 15 ounces. These patients all passed at once into a condition of acute renal toxæmia, but not that form in which fits are predominant. The prognosis in all seemed desperate, yet when once improvement commenced it was very rapid and recovery became complete. The group of cases most resembling these is that in which acute albuminuria develops in the course of specific fevers—for instance, in scarlet fever; but there was nothing of the kind in these cases, unless the influenza of a few weeks previously is to be held responsible. Moreover, cases of such severity following specific fevers are almost invariably fatal.

A CASE OF ANTHRAX.

By EDWARD F. M. NEAVE, M.B., Ch.B.Edin.

Anthrax is such a very fatal disease that any point, however small, bearing on its etiology should be put on record. Though primarily a disease of cattle men are often affected by anthrax, due to accidental inoculation of the virus. In this country the disease occurs in two chief forms, the external or malignant pustule and the internal, of which there are two varieties, the pulmonary and intestinal. Most of the cases of malignant pustule in this country have come under observation at Guy's Hospital, probably owing to its vicinity to the great leather manufactories and tan-yards at Bermondsey and Rotherhithe.

The late Mr. Davies-Colley, to whom we owe a great deal for our present knowledge of the external form of anthrax, says[1] that most of the cases that came under his care at Guy's Hospital exhibited the external lesion or malignant pustule, infection thus occurring through the skin. At Bradford, on the other hand (where the disease goes under the synonym of wool-sorter's disease), it seems that infection takes place through the lungs, most of the cases exhibiting an asthenic form of pneumonia. Outside these two great centres the disease (in man) is not common, but amongst animals epidemics occur now and again in different parts of the country. Anthrax usually attacks animals by way of the intestines, the food being infected by foreign fodder, litter, and manures, or the animals may be infected by feeding on pastures in which the germs have been preserved. The outbreaks on certain farms which occur now and again may be explained by the fact that the spores can live in the earth for an indefinite time.

Malignant pustule usually occurs in men who come into contact with the hides or fleeces of diseased animals or with the diseased animals themselves, the poison gaining entrance through a wound or an abrasion of the skin. Thus we find that butchers, shepherds, and knackers are very liable to be inoculated with the virus of anthrax. In all such cases the infection is, as a rule, easily traced, but there are certain isolated cases which sometimes occur where the infection cannot be easily traced. The following is a case in point. I shall first give the notes of the case and then discuss the interesting features in detail.

The patient was a middle-sized, muscular man, aged 50 years. He came to me on May 6th, 1900, complaining of an itchiness on the left side of the chest. He said that on the previous day he had felt the left side of his chest itchy and had been scratching it. At that time he noticed what he thought was a pimple above the left nipple. Since then the pimple had been growing larger and the skin around had become swollen and inflamed-looking. Otherwise he said that he felt quite well. On examination, on the left side of the chest, two inches above the nipple, there was a ring of small vesicles with a slightly depressed centre. The ring was of about the size of a threepenny-piece. Beyond the ring of vesicles there were slight swelling and redness of the skin. No enlarged glands could be felt in the axilla. The pulse and the temperature were normal. On the 7th the patient seemed to be fairly well, although the vesicles were larger and the surrounding skin was more swollen, redder, and œdematous. He was going about, but he said he did not feel quite able for his work.

When I saw him on the following day (the 8th) I learned that he had had slight rigors and had suffered from slight sickness and vomiting during the night. The vesicles were still larger and had become confluent, forming a large vesicular ring in the centre of which there was a small dark brown eschar of about the size of a pin-head. Round about there were great swelling, induration and œdema. The skin was dark-coloured, being almost black in patches, and the spreading edge of inflammation was irregular. Owing to the swelling and induration no enlarged glands could be felt in the axilla. The spleen was slightly enlarged. The breathing was regular and was 20 per minute. There was no cough. The pulse was 100, regular, and of good quality. The temperature was 99.4° F. On the whole the patient's general condition was fairly good. On the following night he slept fairly well, but next morning he was much weaker and was suffering from dyspnœa and cyanosis. The dyspnœa and cyanosis increased very rapidly and the patient died the same evening (the 9th), his mental faculties remaining clear to the end.

Through the kindness of Dr. McLagan Wedderburn, the medical officer of health of the county, the serum in the vesicles (obtained just after death) was examined bacteriologically and was found to contain large numbers of the anthrax bacilli (bacillus anthracis). Pure cultures were obtained on agar-agar and a guinea-pig inoculated with the serum died with symptoms of anthrax. The following are the interesting features of the case.

1. *The source of infection.*—On inquiry it appeared that there were no suffering animals on the farm or in the neighbourhood, nor was there anthrax amongst animals in the county at this time. As regards the man's work he had been engaged for the fortnight previously to his illness in sowing different kinds of grain along with artificial manure in the form of bone dust. The question is, therefore, Did infection occur from the grain or from the bone dust? The grain that the patient had been sowing three or four days previously to the beginning of his illness was grown on his own farm, and as no case of anthrax has been known to have occurred for a number of years in the neighbourhood, and as the period of incubation of malignant pustule is said to be from two to three days, I think we may put aside the grain as the source of infection. Bone dust, on the other hand, is known as a source of infection of anthrax. A sample of the bone dust which the man had been handling was examined bacteriologically but with a negative result. Notwithstanding this failure to cultivate the organism from the bone dust I am still of the opinion that the bone dust was the source of infection and that the patient had inoculated himself, his hands conveying the infection. This seems the more likely from the fact that the patient had been in the habit of putting his hand underneath his shirt and scratching his breast. On inquiry it appears that the bones from which the bone dust is prepared are imported from abroad. Greenfield[2] says that animals may occasionally

---

[1] Transactions of the Royal Medical and Chirurgical Society, 1882.

[2] Quain's Dictionary of Medicine.

be infected t

have not hea

infected by bone dust directly.

2. *The rapid course of the disease.*—The patient first complained of the itching on May 5th and he died on the 9th—i.e., four days after the onset of the disease. This is about the earliest period at which death may occur, although several cases have been reported in which death took place on the third day. As a rule, however, the disease lasts longer than four days.

3. *The temperature.*—The patient's temperature did not rise above 100° F. Some say that the temperature in malignant pustule does not rise at all. Greenfield[3] says: "This may be true in some cases in which there is no general infection. In other cases, while the surface temperature may be subnormal, the rectal temperature is elevated." Other authorities say that in cases of malignant pustule the temperature never rises above 102°.

4. *The site of the lesion.*—In this case the site of the lesion was unusual, for in no case which I have come across has the lesion been situated on the breast. The commonest sites are the face, neck, arms, and hands. In this

I learned that the patient

ig his breast and it seems

iveyed the infection.

5. *The absence of pain and severe constitutional symptoms*—The absence of pain is of interest as distinguishing malignant pustule from phlegmonous erysipelas, a disease in which there is severe pain and with which malignant pustule is

en in cases

l symptoms

work with a

light degree

absence of

patient and

features to

which many writers refer.

The treatment which I adopted from the beginning was strong carbolic dressings locally and tonics. The majority of surgeons advise excision of the pustule, although it is said there is great danger in the operation in allowing the entrance of the bacilli into the blood stream. Others advise the injection of carbolic acid subcutaneously around the seat of inoculation.

Trinckheim, N.B

ON THE LIMITS OF THE HEART DULNESS IN CASES OF ANÆMIA AND CHLOROSIS.

BY R. WYBAUW, M.D.,

DOCTEUR SPÉCIAL OF THE BRUSSELS UNIVERSITY; ASSISTANT PHYSICIAN TO ST. JOHN'S HOSPITAL, BRUSSELS.

DURING recent years the diagnosis of valvular disease of the heart has undergone a remarkable change. 20 years ago the principal object of the physician was to recognise exactly the seat and the nature of the supposed valvular trouble, and to give a precise anatomical name to it. Nowadays this is no longer sufficient, and much more attention is paid to the state of nutrition and to the function of the heart muscle itself, its strength, and its ability to overcome the increased resistance of the blood.

Normally the wall of the heart, and especially that of the ventricle, has sufficient strength to expel the blood from its cavities into the arterial system, even when the blood-pressure is slightly increased. Of course, if the muscle loses its strength because its nutrition is impaired a complete contraction will be impossible and dilatation will occur. German and Swedish observers have studied minutely the mechanism of "dilatation from overstrain" (Ueberanstrengungs dilatation) in cases of valvular diseases, of general affections, of anæmia, &c. It is produced when the relation between the blood-pressure in the heart cavity (and more particularly in the ventricle) and the strength of the muscle is no longer normal, the latter being unequal to the former. This may occur in two ways: (1) the blood-pressure may be abnormally increased; and (2) the muscle may be abnormally weak and its contraction less effective.

character in many kinds of valvular diseases or of infection (diphtheria, scarlet fever, typhoid fever, &c.), when the nutrition of the muscle cells is impaired because the blood of the coronary system is more venous or less oxidised, or because its chemical constitution is abnormal. In anæmia and in chlorosis the same conditions exist. In them an acute dilatation of the heart has been frequently observed, with or without recovery and return to the normal size of the heart when the disease had passed away. Recovery is, however, not always possible, for it seems probable that a certain amount of hypertrophy may be added to the primary dilatation.

What happens in chlorosis? The cause of the disease is still unknown—it may be a nervous, trophic, or chemical influence; it is certain, however, that many muscle cells, and especially unstriped muscle cells, lose their tonus and consequently the cavities in the wall of which they are contained have a well-marked tendency to dilate. Dilatation of the stomach and dilatation of the intestine are very frequently found. Professor Glax of Abbazia thinks that in chlorosis there is a general infiltration of the tissues by effused blood-serum—indeed, when the condition of the patient begins to improve the quantity of urine increases and the weight diminishes. Even here where the pure air, the walks, &c., cause an increase of weight in normal individuals after a few days passed in Spa, I often saw the weight of anæmic girls diminish whilst the symptoms markedly improved. It is possible that a similar infiltration as supposed by Professor Glax may exist in the heart tissue and cause a diminishing of force leading to dilatation of the organ as well as in the intestine or stomach. Of course no reference is here made to the common symptoms of heart murmurs in anæmia and chlorosis, only the functional strength of the muscle is at present under consideration. It is well known that a marked murmur may be produced by very little change in the heart's condition (accidental murmurs), or the contrary may be found in many cases. The trouble of the heart function itself is only to be detected by percussion, by examining the pulse, or by the use of radiography (Grünmach).

As it is very difficult for practitioners in bath resorts to obtain a complete history of patients, I here give the history of a young girl whom I saw in Professor Destrée's

e was 16 years of age and

1899. Her father died

elf quite well until five

days before her admission, when she suddenly suffered from severe pain in the right hypochondrium and the epigastrium. On examination no other trouble was detected than great anæmia with loss of hæmoglobin and a well marked increase of the heart dulness, relative and absolute. The relative dulness extended upwards to the second rib and downwards to the lower border of the sixth rib. It extended three centimetres (one and a quarter inches) to the right and 10 centimetres (four inches) to the left from the medio-sternal line. Absolute rest was prescribed and the pain disappeared after three days. The patient soon left the hospital, saying that she felt quite well, the area of the heart dulness being little changed. Immediately after leaving she continued her ordinary hard work and was obliged to re-enter the hospital on July 27th. She only complained of pain in the epigastrium and in the left side. Her general state of health was worse. The stomach was neither displaced nor dilated, but the heart extended 11½ centimetres towards the left, and four and a half centimetres to the right. The apex beat was to be felt in the sixth intercostal space. The patient remained three weeks in the hospital. The limits of the heart dulness changed a little (11 centimetres at the left and three centimetres at the right side of the medio-sternal line). There was no tubercle.

In this case the extent of the dulness outwards and downwards without the slightest sign of heart disease, and its rapid increase during the hard work from the end of April to the end of July, clearly indicated the existence of an uncomplicated dilatation of the heart. This question is a very important one, for several German writers, including von Noorden, Müller, and others, think that in chlorosis there is no dilatation but only a displacement of the heart. The dulness would only seem enlarged because the diaphragm in those patients is higher than normal and causes the heart to be pushed upwards, its greater diameter becoming more horizontal and its right border being displaced towards the right, and the apex outwards but not downwards. Grünmach published in the *Therapeutische Monatshefte* the result of radiographic examinations and demonstrated the displacement of the diaphragm in cases of chlorosis and other similar diseases. Such cases, no doubt, exist, but in medical science it is desirable to avoid generalising too hastily. I had recently an opportunity of observing several cases in which the apex beat was really displaced outwards but not downwards; it was even found to be in the fourth intercostal space. I think that in those cases there is no dilatation at all, but I find it imprudent to deny completely the possibility of dilatation in chlorosis Both are possible, and it may be said that in many cases of chlorosis and anæmia there exists a dilatation of the heart cavities causing an increase in the size of the heart dulness, the apex beat being displaced outwards and downwards. On the other hand, dilatation may be only simulated by a displacement of the diaphragm causing the great diameter of the heart to be more horizontal and the apex-beat to be displaced outwards and downwards.

[4] Ibid.

I saw once a very tall youth, aged 16 years, who was in a very bad condition of health which was caused by improper hygienic conditions. He suffered from pain in the epigastrium, and examination revealed only an enlargement of the left ventricle. After several days of absolute rest this dilatation ceased and the limits of the heart became normal. There was no murmur to be heard, but there was cyclic albuminuria which appeared every afternoon. The patient left the hospital after a week's treatment, and soon afterwards (in five weeks) came back with his heart considerably enlarged. Rest and appropriate diet sufficed to restore him a second time, but the cyclic albuminuria remained. Such cases occurring amongst young men may also be considered as a frequent cause of heart dilatation. The muscular wall of the ventricle being in a bad state of nutrition, the blood is incapable of nourishing the muscle cells.

With regard to the treatment in cases of anæmia the greatest importance should be attached to the functional state of the heart. In many cases, especially in commencing chlorosis, walking and other forms of exercise are recommended and often with a good result, but in more advanced cases absolute rest is necessary in order to strengthen the heart and to prevent oppression, &c. It is interesting to notice that in general the patients complain not only of heart palpitation but of pain in the epigastrium. Many of them, having a well-marked heart dilatation, do not notice any abnormal feeling in the præcordial area, and the epigastric pain often disappears when the dulness regains its normal size.

In a bathing-place like Spa, where hydropathic treatment is almost always combined with the internal use of the ferruginous waters, the examination of the heart must never be omitted; indeed, stimulating the circulation and torpid nervous system will greatly help the internal action of the absorbed iron. That combined action, indeed, gives the best result. In cases, however, where the heart is enlarged and the oppression is intense and in some other cases the use of douches may be dangerous, the patient not being able to stand the sudden shock of the water. In such cases baths of natural carbonic acid water are generally found very useful.

Baths of carbonic acid water may be given in cases of chlorosis and anæmia with increase in the area of cardiac dulness. (Palpitation may be nervous and is not a criterion as to the condition of the heart; pure nervous palpitation is often improved by hydropathic treatment with cold water.) As already mentioned the heart becomes enlarged because the blood-pressure is too strong for its feeble muscle. The carbonic acid bath causes a gentle but general action on all parts of the skin. Soon after entering it the patient feels the bubbles of carbonic acid on every part of his body and the skin becomes red, the peripheral vessels are dilated, and the pulse becomes markedly slower and increases in strength. All cutaneous blood-vessels dilate, thereby diminishing the work of the heart. It is, of course, in the same manner that the baths of Nauheim so greatly improve many cases of heart disease—namely, by diminishing the pressure in the vascular system. Indeed, carbonic acid baths, associated with the internal use of chalybeate water, give the best results in the treatment of anæmia with heart weakness. It is necessary to ascertain the extent of the heart-dulness accurately in order to determine whether exercise or rest is required in the treatment or whether douches or baths will be the more efficacious.

CASE OF SUPRA-HEPATIC HYDATID CYST.

BY GEORGE W. DAVIS, M.D., B.S.DURH.,
L.R.C.P.LOND., M.R.C.S.ENG.

THIS was a hydatid of about 25 ounces capacity situated between the liver and the diaphragm. The diagnosis was difficult even beyond the generality of hydatids. The patient had a healthy appearance and there was an absence of any concrete symptoms other than that of the percussion outline and skiagram.

A symptom of remarkable character was the diminished urination, almost amounting to anuria, which in association with menorrhagia and slight swelling of the legs was evidently due to pressure on the vena cava by the cyst, probably at the point of the passage of the vein through the diaphragm.

In spite of the apparent well-being of the patient her life was imperceptibly but very definitely ebbing away. She was very gradually losing strength and energy; from being a woman who took an active part in the household management she could merely lie on her bed or sofa, walk short distances, and go about in a bath chair, and even this slight exertion was accomplished with increasing difficulty.

The case was seen by Sir William Broadbent, Bart., by Mr. Charters Symonds, by Mr. Golding-Bird, by Mr. G. H. Makins, by Mr. F. G. Larkin, and by Dr. Barry Blacker. She was first seen by me on Nov. 12th, 1898 The operations were performed on April 12th and 16th, 1899, by Mr. G. H. Makins and the convalescent period extended over two and a half months, during the whole of which time there was much danger of septic infection from the character of the walls of the cyst which kept it gaping and in continual movement.

The patient was a multipara, aged 36 years, and had four healthy children between the ages of seven and 16 years. Her father died from enlargement of the liver at 60 years of age, her mother died from "cancer" at 60 years of age, and an aunt is suffering from multiple abdominal tumours the character of which have not been diagnosed. She has eight brothers and two sisters alive and healthy. Except for confinements and three miscarriages the patient had never ailed until 1894 when Mr F. G. Larkin discovered the abdominal hydatid which was removed by operation in two stages by Mr. Charters Symonds.

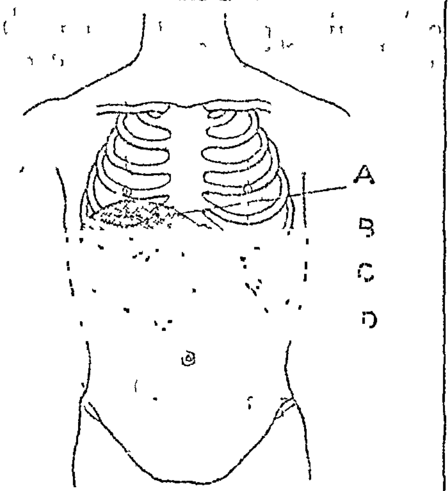
On Nov. 12th, 1898, I was first consulted on account of blood passed by the bowel, apparently due to some obstruction of the vena portæ This led to a careful examination of the liver, but it will be easier to grasp the main facts of the case by reviewing the chief symptoms separately during the period of five months preceding the operation, then describing the operation, and afterwards the convalescence.

The patient was fair-complexioned, fresh in colour, very young looking, and had such an appearance of absolute health that it was extremely difficult to impress upon the minds of those who saw her for the first time that actually she was seriously ill—as a matter of fact, fading gradually both as to weight and strength. Her weight in November, 1898, was 8 st 12 lb, and in April, 1899, it was but 8 st. The difficulties of obtaining recognition of the gravity of her condition were further increased by the fact of her occasional improvement in health. Thus at one time she regained 4 lb.

The entire right chest was rather more prominent than the left chest, the measurements being 15⅛ inches on the right side and 14¼ inches on the left. The dulness of the liver by percussion—the arms being extended by the side of the head—was seven inches vertically in the middle line, five inches on the right side of the ensiform cartilage, and five inches in the posterior axillary line. The dulness could not be defined posteriorly. I found that I could percuss out the liver much more correctly when standing to the left of the patient (Fig. 1).

The dome-like character of the cyst made it difficult to define by percussion and in February I had a skiagram taken by Dr Barry Blacker which [illegible] the diagnosis by percussio[illegible] globular outline of the cyst (Fig 2). Pain was felt occasionally at the side of the right chest and any pressure on the

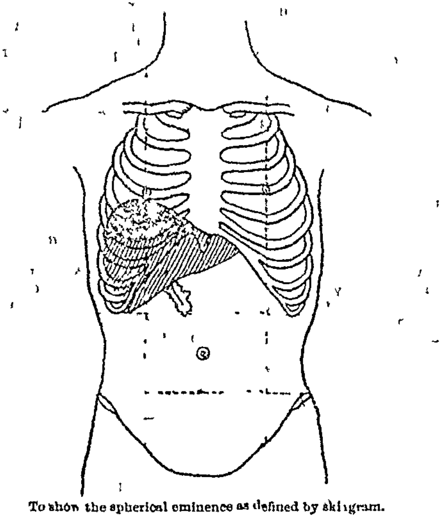
FIG 1.



A, Actual line of dulness B Normal liver outline C, Actual line of dulness D, Scar of previous operation

liver below the ribs caused much pain The patient's loss of energy may be estimated from the fact that in June, 1898, she cycled for four miles on several occasions, but by March, 1899, she could only walk with difficulty and even bath chair exercise exhausted her so much that she came

FIG 2



To show the spherical eminence as defined by skiagram.

home blue about the lips, faint and miserable. Menstruation was *much more profuse and often the flow would* occur in gushes

The diminution of urine passed was a most remarkable symptom and was doubtless due to pressure by the cyst on the vena cava as it passed through the diaphragm, causing [illegible] no conjugative sweating The urine was of average specific gravity and contained no abnormal constituents The amount of urine passed in 24 hours was as follows —

—	Number of observations	Average ounces.	Maximum ounces	Minimum ounces
November, 1898	9	18	28	18
December, 1893	17	12¼	20	5
January, 1899	24	12½	24	4
February, 1899	24	14	25	6½
March, 1899	24	10	19	3

The amount of fluid taken at this time averaged about 30 ounces in 24 hours

Her temperature ranged between 96 4° and 98° F, but was subnormal for the entire period The approximate averages were as follows —November, 93°, December, 97 8°; January, 97 5°, February, 97 6°, and March, 97 4°. The pulse, which was poor in quality, was very constant, about 72 The respiration was about an average of 22 The nervous symptoms may be described as some increase of the left knee reflex, much vertical headache, and sleeplessness

As already mentioned, the operations for the removal of the cyst were performed on April 12th and 16th, 1899, by Mr G. H Makins The [illegible] d in the usual manner at 9 30 [illegible] inis tered by Mr Walter Tyrre[illegible] was *made below the ensiform* cartilage and through this the lower surface of the liver was explored with negative result as to any secondary cyst A long exploring needle was now thrust into the liver and at the fourth thrust sufficient fluid was obtained to confirm the diagnosis by the discovery of many booklets The central incision was now closed and about two inches of the seventh rib were resected in the right mid axillary line, the intercostal muscles and both parietal and visceral layers of the pleura were divided and stitched around the opening left by the resection of the rib, leaving the cyst wall apparent On April 16th Mr Walter Tyrrell gave the anæsthetic at 11 30 A M A crucial incision was made into the *cyst to the extent of the opening, and from 25 to 30 ounces* of lemon coloured fluid came away No daughter cysts were present The hyaline cyst floated free within the cavity and was so friable as to be with difficulty removed by means of ovum forceps The cavity was six and a half inches across. A large drainage tube was put right into it and the whole was dressed in the usual manner The temperature rose until on April 19th it reached 103° and did not become normal until May 9th An ice cradle was kept on whenever *the temperature reached 100° until April 25th* On April 24th I aspirated in the sixth space at the back of the right chest and removed two ounces of highly coagulable fluid Sloughy pieces of cyst wall continued to come away until a month after the operation The cyst cavity was prevented from bridging over and closing superficially before it closed deeply by gauze packing and by the drainage tube being kept in for a long time (it was not removed until June 3rd, 1899) Twice daily for five weeks I syringed the cyst out with solution of creolin (1 in 160) and then introduced some emulsion of europhen in glycerine and iodoform gauze All dressings were sterilised by steam before use throughout the convalescence The right chest was strapped *from May 12th onwards until the sinus completely* closed

On June 19th the patient left for the seaside and passed from my observation for a month and at the end of that time she was completely cured

This case appears to be important to record for two reasons Firstly, it well illustrates that the history of a case of hydatid is often that of a deterioration of health so gradual as to be imperceptible to the patient's friends, but which is measurably demonstrable if a strict record of the patient's powers is taken at intervals If this deterioration is not arrested, by removal of the cyst, before the patient has become too weak to bear the exhaustion entailed by a necessarily debilitating convalescence the end of such a case, apart from suppuration or bursting of the cyst, must be death after the failure of force has gradually deprived the victim of function by function until the whole gamut has been passed from perfect enjoyment of full energy to a mere bedridden existence. The second point is of extreme interest physiologically as showing the marked diminution of urinary secretion which follows obstruction to the venous outflow from the kidney by pressure on the inferior vena cava.

TOTTENHAM HOSPITAL.

A CASE OF AN UNUSUAL FORM OF INTUSSUSCEPTION.

(Under the care of Mr. HERBERT W. CARSON.)

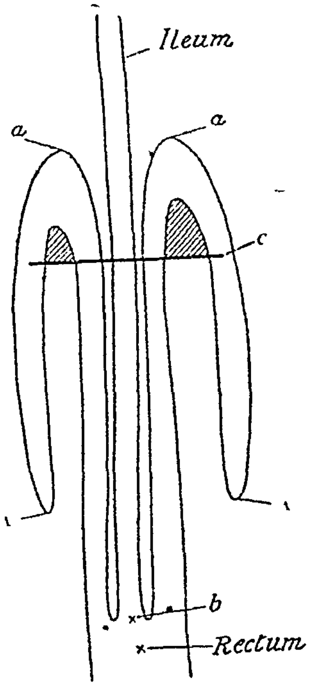
IN infants under the age of six months intussusception is always a very serious condition, even though laparotomy be performed early, but if when the abdomen has been opened it is not possible to reduce the intussusception the prognosis is extremely grave, for whatever method of treatment be adopted a fatal result is almost certain to ensue. Three courses are open to the surgeon: in the first place he may incise the ensheathing layer and may then excise the included bowel; or secondly, he may excise the whole intussusception, performing anastomosis between the healthy bowel above and the healthy bowel below; or lastly, a portion of the bowel immediately above the invagination may be brought up to the surface and an artificial anus made. Inasmuch as shock is the main cause of death after operation for intussusception in infants it is probable that the last method will give the best results. The complexity of the intussusception in the case recorded below is indeed remarkable.

A female, aged five months, was admitted into the Tottenham Hospital on May 14th, 1900, with an abdominal tumour and a history of passing blood and mucus. The child was quite well till the 9th, when she had diarrhœa; passed a little blood, and "the bowel came down." This was replaced by the mother who then obtained medical advice. No tumour was then felt in the abdomen; the child looked fairly well and was not sick. On the 12th the bowels acted and the child vomited after a screaming fit. There was no further sickness before admission to the hospital, but slime and blood were passed per rectum on the 13th and 14th (the day of admission).

On admission the child was quiet, the pulse was fair, and her general condition was good. There was no abdominal distension. A definite small tumour was felt in the left lumbar region above and internal to the anterior superior spine. Per rectum the sphincter was found to be relaxed. The presenting part of an intussusception was felt just above the internal sphincter having two openings, the lumen of the bowel and the mouth of the appendix. As seen per speculum the presenting mass was of a brownish-grey colour. An unsuccessful attempt had been made to reduce the intussusception by injections.

Under chloroform the abdomen was opened a little to the left of the middle line and the intussusception was easily found in the situation of the lower part of the descending colon. It measured some five or six inches in length. At the upper end the ileum entered the intussusception and the lower end presented an almost identical appearance, with the exception that the rectum took the place of the ileum. Attempts at reduction proving unsuccessful the tumour was drawn outside the abdomen and shut off from the peritoneal cavity, and the intussuscipiens was opened by the longitudinal incision recommended by Barker, the ileum and ensheathing layer having been first united by interrupted sutures. The intussusceptum was then cut through *in situ* at the upper part, as it was impossible to bring it through the incision. This resulted in freeing a deeply congested portion of bowel about two inches long having the mucous membrane external. The rectum was then easily reduced and clamped. The intussuscipiens was then found to consist of four layers measuring 15 inches when unfolded. The upper and lower ends of this at the ileo-cæcal junction and at the junction of the colon with the sigmoid flexure were so congested that there was no alternative but to excise the whole of it. This was done and the ileum was united to the rectum over a bone bobbin. The patient died about an hour after returning to bed.

Remarks by Mr. CARSON.—This case seems to be a good instance of those rare cases of intussusception in which "a descending intussusception is associated with an ascending one, the two occupying the same segment of bowel."[1] The accompanying diagram will make the condition clearer, the intervals between the layers being left for the sake of clearness. In the present case the descending intussusception was of the ileo-cæcal type, the ascending one being of the colic variety, and thus differs from the case quoted by Mr. Treves[2] in which the descending and ascending intussusceptions were both colic in origin. Mr. Treves also quotes from Leichtenstern who gives eight cases of double intussusception, and from M. Besnier and Nothnagel, in the latter cases the double intussusception being in the large intestine and occurring in cases of chronic obstruction. The only case I can find in recent literature which at all resembles the one detailed above is that described by Mr. W. H. Brown[3] in which an ileo-cæcal (?) intussusception was complicated by a short longitudinal fold of the intussusception on itself. The dilatation of the sphincter so often noted in cases of intussusception was well marked in this case. It would be interesting to know whether in replacing "the bowel which came down" the mother really reduced a mere prolapse of the rectum or pushed back the advancing apex of the intussusception. Taking into consideration the condition of the child on admission it seems improbable that the apex of the intussusception could have been at the sphincter from the 9th to the 14th (six days), though the condition of the bowel itself pointed to a somewhat prolonged strangulation.



a and x were firmly adherent to ileum and rectum respectively. *b*, Ileo-cæcal valve *c*, Incision *in situ* freeing the small shaded part.

ST. MARY'S HOSPITAL, MANCHESTER.

A CASE OF CÆSAREAN SECTION IN A PRIMIPARA ON ACCOUNT OF THE PELVIC CAVITY BEING BLOCKED BY A FIBROID TUMOUR OF THE UTERUS; RECOVERY; CHILD LIVING.

(Under the care of Dr. LLOYD ROBERTS.)

IN the following very interesting case of Cæsarean section the employment of anti-streptococcic serum seems to have

---

[1] Treves: Intestinal Obstruction, p. 152.

[2] Ibid.

[3] THE LANCET, August 20th, 1898, p. 484.

[illegible] septic temperature, but the [illegible] been much enhanced if an [illegible] the presence of any micro- [illegible] this was merely a case of [illegible] serum cannot be credited with the improvement, while if a streptococcus was really present in the patient's blood we should be justified in thinking that the serum had had an important share in bringing about the recovery. It is only by exact observations in every case that we can arrive at any trustworthy estimate of the value of anti-streptococcic serum. For the notes of the case we are indebted to Dr. J. S. Ross, house surgeon.

A married woman, aged 34 years, was admitted into St. Mary's Hospital, Manchester, on April 30th. The patient had been married 12 months and up to July, 1899, menstruation had been regular every four weeks, the duration of the flow being three days, rather copious in amount, but not accompanied by dysmenorrhœa. She had slight leucorrhœa. In July menstruation ceased suddenly and the patient presumed that she was pregnant. Up to the time of labour beginning she was unaware of anything abnormal. On April 29th, 1900, at 11 P.M. the pains began and on April 30th Dr. J. A. W. Watts of Hyde examined the patient and on his recommendation she was removed to St. Mary's Hospital. On admission the patient had a normal pulse and temperature. The abdomen had the appearance of normal pregnancy at about nine months and the fœtal heart was heard. Per vaginam the posterior fornix was filled with a hard mass which was quite fixed in the pelvis, the os could just be touched very high up in front; only about one and a-half inches of conjugate was left. Per rectum the retro-uterine mass was made out to be separate from the bony pelvis; it was in front of the rectum.

On May 1st ether was administered and an incision was made into the abdominal wall from the umbilicus to the pubes. The uterus was incised in the middle line and the placenta was found to be attached to its anterior surface; the membranes were opened, and the fœtus, a living male of about eight and a half months was extracted by the leg. The placenta was now detached, all clots and remains of membrane were removed, and the uterus after being lifted through the abdominal opening was compressed, its edges being brought together with interrupted silk sutures passed through the peritoneum, uterine muscle, and mucous membrane. The pelvic tumour was found to be a fibroid growing from the posterior wall of the uterus; it was so firmly adherent to the rectum and to the sigmoid as to preclude removal; whilst investigating the attachments of the tumour considerable bleeding occurred from its fleshy pedicle and a number of silk sutures had to be used to arrest it. The abdomen was closed with silkworm gut and a gauze drain was pushed from the vagina into the uterus.

The after progress was fairly satisfactory up to May 4th when the pulse ran up to 130 and the abdomen was slightly distended; the lochia, which had never been very profuse, were rather fœtid. On the 7th the patient was still very ill, the abdomen, though distended, still moved with respiration; the bowels had been kept constantly loose with calomel and with turpentine enemas. Anti-streptococcic serum was injected at 6 P.M.; the temperature fell in four hours from 104·2° to 100·6° F. and the pulse from 140 to 130. On the 8th the temperature rose again in the evening to 103·6°, the pulse varying from 130 to 140. One grain of calomel was ordered every four hours. On the 9th the note is as follows: "Condition about the same; the highest temperature at 6 P.M. 103°, and at 10 P.M. the serum was again injected; the temperature fell from 101·2° to 100·8°; the pulse remained about 130. The abdominal wound had been dressed and a little suppuration was noticed along the lowest two sutures." From the 11th to the 20th the patient improved slowly but steadily; no more serum was used, but quinine was freely given; the temperature ran up occasionally to about 101°, but the pulse fell to 120. After May 31st the temperature never rose above 100°, but it was not thoroughly normal throughout the day until the middle of June. Since then the patient has steadily improved. The uterus has shrunk to a hard mass still quite fixed in the pelvis. The child was fed artificially and is healthy.

Remarks by Dr. LLOYD ROBERTS.—Cæsarean section was performed in this case because the pelvic cavity was blocked by a fibroid tumour of the uterus so that the conjugate diameter was reduced to one and a half inches, rendering even cephalotripsy impracticable. The tumour sprang from the posterior wall of the uterus, and it was my intention to remove it at the time of the operation but it was found to be so firmly adherent to the rectum and the sigmoid flexure as to prohibit any further interference. The uterus was not drawn through the abdominal wound until it was opened and emptied of its contents. This procedure allows of more easy manual compression and thus prevents hæmorrhage; it also facilitates accurate suturing of the uterine wall and a thorough cleansing of the abdominal and pelvic cavities. The sutures used were of silk and they were passed through the peritoneum, the uterine muscle, and the mucous membrane. No abdominal or pelvic drainage was adopted, but the uterus was packed with gauze through the vagina. The acute sepsis which occurred was, I think, benefited by the injection of anti-streptococcic serum.

Reviews and Notices of Books.

Leçons sur les Maladies du Sang. (*Lectures upon the Diseases of the Blood.*) Par GEORGES HAYEM. Paris: Masson et Cie 1900 8vo, pp. 700, with four Coloured Plates. Price 15 francs.

THE book before us contains a series of 44 clinical lectures by Professor Hayem who is a well-known worker upon the blood and its diseases. These lectures are reported by M. Parmentier and M. Bensaude and many of them have appeared in the French medical journals.

After a preliminary lecture upon clinical instruction and another suggested by the death of M. Pasteur upon the importance to the medical profession of the work of that eminent investigator, Professor Hayem commences the subject upon which he is more strictly engaged by a lecture on intravenous saline injections He deals with transfusion more particularly in relation to cholera, but other infections in which it has been looked upon as useful are also mentioned. He figures and describes a simple apparatus devised by his pupils M. Hallion and M. Carrion The next subject dealt with is entitled Considerations upon the Origin of Serum-therapy, but Professor Hayem's treatment of this important matter is somewhat disappointing.

In Lectures IV. to VIII. the examination of the blood is described. The author obtains sufficient blood by pricking the finger and letting the blood drop into a small sterilised glass vessel which holds from 2·5 to 3 cubic centimetres. The mode of flow, the characters of the blood as a whole, its coagulability, and the characters of the clot and serum are carefully noted. The methods of fixing and staining blood films are next given. Long ago Professor Hayem divided the leucocytes into (1) the translucent and colourless mononucleated; (2) the opaque and coloured mononucleated; (3) the polynucleated; and (4) the coarsely granular white globules, and he prefers this classification to that of Ehrlich. Among the red cells much importance is attributed in this book to the so-called "hæmatoblasts" in the pathology of some blood diseases.

A very full consideration is given to the subject of chlorosis in Lectures IX. to XVII. The relations of this disease to tuberculosis, Bright's disease, and gastropathies are described in detail. Some curious cases of chlorosis are also related in which death took place through obliteration of the pulmonary artery. The discussion on the nature of chlorosis adds little to our present very imperfect knowledge of this subject. Professor Hayem divides its treatment into (1) rest, (2) gastric treatment, and (3) suitable iron preparations He believes in the use of small doses of iron and recommends the protoxalate, the daily dose not exceeding from 15 to 20 centigrammes.

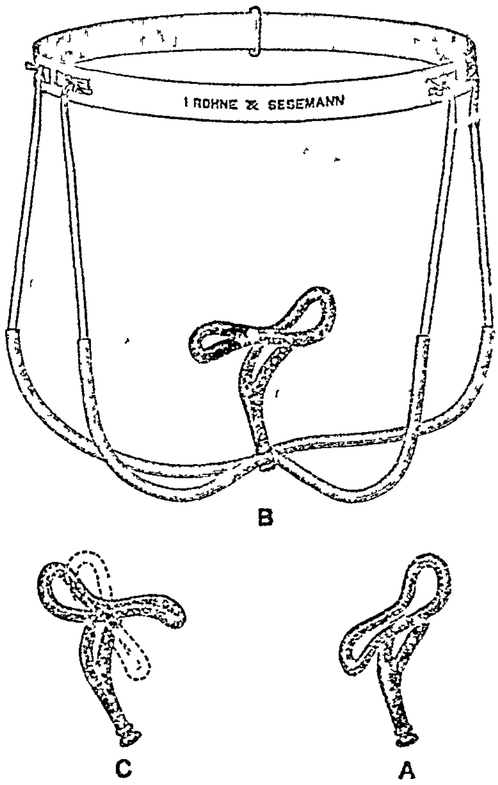
The eighteenth lecture deals with Progressive Protopathic Pernicious Anæmia. The characters of the blood in this disease are extreme deglobulisation, irregularity in the diameter of the red cells, and diminution in the number of

The Quarterly Journal of Microscopical Science. Edited by E. Ray Lankester, F.R.S., Adam Sedgwick, F.R.S, W. F. R. Weldon, F.R S., and Sydney J. Hickson, F.R.S With Lithographic Plates and Engravings on Wood. London: J. & A Churchill. September, 1900 Vol. XLIII. Part 4. Price 10*s.*—The articles contained in this part are: 1. Hippolyte Varians: a Study in Colour Change; by F. W. Gamble, D.Sc., Owens College, Manchester, and F. W. Keeble, M.A., Caius College, Cambridge; with five plates. In this interesting paper the remarkable faculty possessed by a species of prawn of changing its colour in accordance with the prevailing tint around it has been carefully observed. Specimens of this prawn are shown *in situ* clinging to various forms of seaweed and so closely simulating the colour of the weed, whether green, brown, or red, that close inspection is required to recognise their position. The rate of change is slow and takes place even in the dark, though much more rapidly in light. At night the general tint is blue; as day breaks and proceeds other colours appear, so that there is distinct periodicity due to the action of light; variations of temperature and electrical currents also induce changes of colour in these animals. The second article is by Edwin S. Goodrich, M.A, Aldrichian Demonstrator of Comparative Anatomy, Oxford, and is devoted to the consideration of the Nephridia of the Polychæta. It is illustrated by six plates. The author describes the nephridia of Alciopinæ, Phyllodocinæ, Syllidæ, Amphinomidæ, and Polygordiaceæ, and gives a general *résumé* of the most important facts described in this part and in two papers published in preceding numbers of the journal. 3. The last article is entitled "Nouvelles Observations sur les Peripatus de la Collèction du Musée Britannique," par E. L. Bouvier, Professeur au Muséum de l'Histoire Naturelle de Paris. The title and contents of the forty-third volume conclude the part.

New Inventions.

A NEW PESSARY.

The new instrument which I wish to introduce to the profession is our old friend "Hodge" in a new, and I deem an improved, guise, hinged, and with a stem. That there exists no satisfactory pessary for prolapsus uteri in its worst form or for ante-version or ante-flexion is, I believe, incontrovertible. In cases of prolapsus uteri "cup and stem" pessaries, temporarily convenient, are in the end failures. Probably the ulcerated os has been caused or aggravated by their use; besides, they mostly retain foul secretions, become merely vehicles for absorption of septic matter, and at the best are uncomfortable in use. Again, most of them subject the uterus and appendages to violent shock in any undue movement of the body, whilst the bladder and rectum are both, in many mechanical appliances, interfered with In my instrument I claim: 1. Simplicity in construction and, therefore, that it is easy in application and practically aseptic. 2. The hinge action—in deviation about from 75° to 90°—simulates and acts harmoniously with the swing of the broad ligament and thereby lessens or annuls the danger of shock to the organs on impact upon the stem. 3. Neither bladder nor rectum are interfered with, and the dragging down and prolapse of the former are absolutely prevented This hinge action in the ante-version and ante-flexion pessary is checked at a certain angle so that no pressure can act on the bladder; and in the pessary for retro-version or retro flexion the same holds good, and the driving down of the posterior limb upon the rectum is avoided, pressure acting instead along the stem and therefore upon the rubber supports and waistband. 4. Although I have for the present adopted "Hodge" as a model I shall probably modify its shape, as with the forked and hinged stem I can, if necessary, adopt a ring pattern. The whole apparatus can be self-applied by the patient with very little instruction from the medical attendant, and it can be easily cleansed. Old ulcerations induced by friction from badly-fitting pessaries or from external violence are soon cured, as by its use all pressure in the neighbourhood of the ulceration is removed. The size of the pessary, its length of stem, &c., can, of course, be modified to suit each particular requirement. My instructions and ideas have been carried out in a most satisfactory manner by Messrs. Krohne and Sesemann who have spared no trouble in order to meet my wishes.



A, Ante-version pessary ready for insertion. B, Ante-version pessary *in situ* C, Retro-version pessary range of hinge movement.

Hughes R. Davies, L.R.C.P. Lond., M.R C.S. Eng.
Bow, E.

Diphtheria in Leicester.—The outbreak of diphtheria in Leicester continues to increase, 73 fresh cases and nine deaths being notified the week before last, as against 58, 54, and 39 notifications for the three preceding weeks, the resultant mortality in the latter case being 13, nine, and nine respectively. At Tuesday week's meeting of the Leicester Town Council the Sanitary Committee reported that 444 cases of the disease had been notified during the quarter, compared with 212 for the June quarter. The mayor, who is chairman of the committee, said that Mr. H. G. H. Monk, the medical officer of health, had visited every case of diphtheria which had been notified and had given it as his opinion that there was no cause for the disease, but that it spread from one child to the other. The mayor added that the Sanitary Committee were working in harmony with the School Board in the matter and strict injunctions had been given to see that children coming from a house where there was diphtheria should stay away from school for a month —Councillor Hincks said he understood that one of the most fruitful sources of spreading diphtheria was the children's love of cats. That being so it might be well to get rid of the cats.—Councillor C. F. Bryan. M R C S, was afraid that if they got rid of the cats mice would spread the disease. Another cause of spreading the disease was to be found in the slates used by the children at school. The children licked their fingers for the purpose of cleaning their slates and in that way the disease was often communicated.

THE LANCET.

LONDON: SATURDAY, OCTOBER 6, 1900.

It is somewhat surprising that bacteriology should so far have done but little to advance our knowledge of those common infectious fevers which are constantly breaking out in epidemic form in our midst. Many have been the efforts made to discover the specific germs of measles, rotheln, small-pox, and scarlet fever, but so far without success The discovery of the germ of scarlet fever has been announced so often that every new claimant must be prepared to be received with a considerable amount of scepticism. Most of the germs which have been put forward as the microbes of scarlet fever have been described as streptococci, the principal exception being a rod-shaped bacillus found by Edington. Streptococci are certainly very frequently present in the exudation on the throat and in secondary lesions such as otitis media, and recently they have been found by Courtois in the urine of patients suffering from scarlet fever; but there has been nothing distinctive about the streptococci ordinarily met with in scarlet fever and it has been practically impossible to differentiate them from the streptococcus, pyogenes and the streptococci of erysipelas. The organisms described by Klein in connexion with the now historical so-called "Hendon cow disease" were also not to be distinguished from streptococcus pyogenes. The whole matter was dealt with at great length by Professor Crookshank in his reports to the Agricultural Department of the Privy Council, and the arguments against Klein's streptococcus as the cause of scarlet fever seemed to be overwhelming. There are still, however, some who look upon Klein's streptococcus as the specific microbe of the disease. Dr. M. H. Gordon in the twenty-eighth annual report of the medical officer of the Local Government Board refers to the streptococcus scarlatinæ and says that it is acknowledged to be probable that those persons alone who have this streptococcus in their throats are able to infect others. As far as we are aware, however, no proofs have ever been brought forward that the so-called streptococcus scarlatinæ is capable of producing scarlet fever We drew attention nearly a year ago[1] in these columns to the preliminary announcement by Dr. William J Class of Chicago of his discovery in cases of scarlet fever of a diplococcus having a peculiar morphology which he believed to be the long-looked for specific germ of the disease. Dr. Class's further communication on the etiology of scarlet fever which appeared in The Lancet of Sept. 29th (p 927) is of such great importance as to demand some special notice.

The microbe described by Dr. Class has a special morphology which cannot be said of the previously described streptococci. When grown on a special medium it assumes a form resembling a very large gonococcus. The special medium is earth agar, which is glycerine agar to which is added about 5 per cent of black garden earth previously sterilised by discontinuous heating. This form is not constantly met with, but it can always be obtained by successive transplantations on earth agar. The biscuit-shaped appearance is best seen in lightly-stained specimens. In very old cultures grown under favourable conditions the microbe has the appearance of an enormous coccus having a slightly cupped contour, the dividing line between the two portions being very indistinct in the more deeply stained specimens Smaller organisms arise by division of the large diplococcus and may group themselves together. While the form is very constant when the germ is grown on the special medium it is capable of very great variability when grown in different media. Sometimes it forms chains, sometimes clusters, sometimes resembling a streptococcus, sometimes a staphylococcus Its one distinguishing morphological feature appears to be its diplococcus form when grown on earth agar. Long chains have never been obtained by Dr. Class, in an experience of hundreds of cases, from uncomplicated cases of scarlet fever. It is quite possible, as Dr. Class suggests, that the same organisms have been previously observed and described by some as streptococci and by Crajkowski as diplococci, but to find a germ in a certain disease and to establish its relation to that disease are two very different matters

Dr Class next maintains that this diplococcus is constantly present in scarlet fever He has found it in 300 successive cases and his findings have been confirmed by Grodwohl and Jaques. He says that he is absolutely certain of his ability to demonstrate the presence of the diplococcus in the blood, throat secretions, and scales of every typical case of scarlet fever. Assuming the accuracy of these observations that the organism is a constant feature of cases of scarlet fever we have next to be satisfied that it is the cause of the disease. To demonstrate this in a satisfactory manner is a very difficult matter. It is not possible experimentally to inoculate a human subject with a culture of the diplococcus with the object of seeing whether it will produce scarlet fever. We have at present no certain way of recognising scarlet fever, if such exists, among the lower animals. There is nothing characteristic in the morbid anatomy of scarlet fever in the human subject, and we are still less in a position to affirm from post-mortem examination of an animal that it presents characteristic lesions of scarlet fever.

What Dr. Class has established in the case of the lower animals, however, amounts to this—that the organism is pathogenic to mice, swine, and guinea-pigs. Mice are most susceptible, death as a rule following within 12 hours after subcutaneous injection of a small quantity of a virulent culture. Swine are unaffected by subcutaneous injections except when a very large quantity of a virulent culture is used, but intra abdominal injections are followed by grave symptoms and even death. Intravenous injections, however, are the most certain. Guinea-pigs are killed by intra-abdominal injections of virulent cultures. The diplococcus can, as a rule, be recovered from the bodies of the affected animals.

In white swine Dr. Class has succeeded in producing by intravenous injections of virulent cultures of the diplococcus a disease resembling scarlet fever. The injections produce malaise and rise of temperature within a few hours. In three or four days there is reddening of the skin followed after a week or two by profuse scaling. Sometimes the eruption is papular rather than erythematous. A considerable number of experiments were made with the same result.

---

[1] The Lancet, Nov. 18th, 1899, p. 1385

We do not attach very much importance to the statement that the post-mortem appearances resembled those of scarlet fever. Similar appearances were observed by KLEIN as the result of inoculation with cultures of the Hendon streptococcus. Nephritis and enlargement of the spleen cannot be said to be peculiar effects of the scarlatinal poison. Nor can we draw any important conclusion from the fact that the disease inoculated in swine and mice appeared to be of a contagious nature—healthy animals placed with inoculated animals contracting similar affections — for this is a probable result in the case of any inoculable disease.

The observations made as to the influence of the blood of patients just recovering from scarlet fever on the activity of the germ are of interest. The blood inhibited to a certain degree the growth of cultures, and mice treated with subcutaneous injections of blood serum survived longer after inoculation than the other animals. These results lend further support to the contention that the diplococcus is the germ of scarlet fever. It would be still more convincing if it were found that the blood of patients suffering or recovering from scarlet fever had an agglutinating effect upon homogeneous cultures of the diplococcus.

Two further observations are brought forward by Dr. CLASS in conclusion. The first is that the diplococcus is found not only in cases of undoubted scarlet fever but also in cases of scarlatinal sore-throat and in cases of surgical scarlet fever. If, therefore, the diplococcus is the germ of scarlet fever, the nature of these hitherto debateable diseases is established. The second is that the diplococcus will grow in milk without producing any visible change in it. Many epidemics of scarlet fever have been connected with milk, as was the outbreak in Marylebone, which was traced to the milk distributed from the dairy farm in Hendon. It is accordingly in the highest degree probable that the germ of scarlet fever does not sensibly alter the appearance or the character of milk. The fact that the diplococcus does not alter milk in which it grows is not only consistent with, but also in favour of, the view that it is the specific germ.

Although it cannot be said to be proved absolutely that the diplococcus discovered by Dr. CLASS is the specific germ of scarlet fever all the evidence so carefully collected points in this direction. The streptococcus recently described by ADOLPH BAGINSKY and PAUL SOMMERFELD before the Berlin Medical Society and in the columns of the *Berliner Klinische Wochenschrift* as constantly present in the throat secretions and blood of patients suffering from scarlet fever may possibly be the same microbe as that discovered by Dr CLASS, but Dr. CLASS has pushed his investigations much further than have the German observers, and we trust that he will be able successfully to complete the work which he has so far advanced.

WHATEVER success may attend the appeal of the late Government to the nation on the questions of war and of the future of South Africa it will do well to take notice that equally great questions within the sphere of domestic politics will demand the attention of Parliament in the immediate future. Not only so, but the credit of the new Ministry (however it may be constituted) and its claim to the gratitude of the nation and of posterity will depend as much on its attention to these questions affecting our own people as on its foreign policy. Indeed, it is not too much to say that a foreign policy which absorbed all the attention of the country and of the Parliament and allowed no time for consideration of both the physical and moral health of the people would stand self-condemned. Of such questions none can exceed in importance that of the housing of the working classes. Much admirable work has been done of late years by the London County Council and by other bodies in multiplying open spaces in the metropolis and other large towns. But this is of little avail unless the living space within and about houses—that is, the space necessary for health and morals—can be increased. The open spaces are available as playgrounds only on holidays and at rare intervals and can tell comparatively little upon health, but an increase in the cubic space allowed for each member of a household in living-rooms and bedrooms would effect immediately a reduction of mortality both from tuberculosis and the ordinary epidemics and would bring an enormous accession to the brightness and pleasure of life among the poor. This may seem a trite and common-place object to occupy statesmen and politicians. But he is a superficial observer who thinks it so and there are evidences on all sides that it is one the furtherance of which is exercising the mind of the nation.

During the late session the Government showed some sense of the importance of the subject by bringing in, and passing, a Bill the main provision of which was one to enable local authorities to establish or acquire lodging-houses for the working classes outside their respective districts. The Manchester City Council lately adopted a report for the purchase of 237 acres for this purpose at a distance of four miles from that city. The Northamptonshire County Council under the Housing of the Working Classes Act (1890) recently agreed to sanction the adoption of Part III. of that Act by the Brixworth District Council in respect of a Northamptonshire village named Spratton. Towering high above all parties and the mere politics of parties are the words of His Royal Highness the PRINCE OF WALES: "There is no question at the present time of greater social importance than that of the housing of the working classes. ..... I hope the Legislature will be able to deal with the case of those who are responsible for insanitary property." The nation cannot but feel grateful to the PRINCE OF WALES for boldly giving utterance to such sentiments, which are worthy of him, as they would have been worthy of his illustrious father. The Church Congress, too, has shown its sense of the gravity of this subject by finding a place for it in its proceedings at the recent meeting at Newcastle. The Rev. J. W. HORSLEY was the principal speaker, and he adduced some of those terrible statistics that disturb the complacency with which we are too apt to regard our boasted civilisation. In his civil parish 124,000 people live on less than a square mile. There are nearly half a million persons in London in whose case home consists of one room; of 4575 one-roomed tenements in Spitalfields 1400 are occupied by from four to seven persons. He adduced other instances, such as the following: 17 persons in one room in Clerkenwell; 3000 persons to an acre through the agency of industrial dwellings in one part of Whitechapel; whole families in workhouses because the fathers, though in work, cannot find rooms; the large profits of slum landlords, illustrated by a six-roomed tenement in a city slum inhabited by six families at 6s. a week each, equal to £93 12s. per annum for a cottage in an alley, and much more to the same effect. To expect purity and health and temperance in such conditions is to expect to gather grapes of thorns or figs of thistles.

It is more easy to depict the evils of such a state of matters than to assign blame. But surely there is blame in all directions; ARTHUR HELPS thought that much was attached to architects and builders, and declared that they had made less advance since the time of the Romans than any other class. The slum owners are amongst the principal culprits; we have seen how exacting they are in the matter of profits and we know how careless they are apt to be in respect of the sanitary conditions of their property. The State has been too fastidious in regarding the rights of the property owner and too slack in insisting on his duties. It seems a mere truism to say that a house should be safe to live in both as regards its size and its appointments, and a matter of course to require that the landlord should be punished for any gross defect in this respect. Instead of this much of the legislation that has been passed has been of such a nature as to pay the landlord far above its value for his rotten and defective property. The best remedy for this will be in the more severe application of scientific and medical tests of the sanitary value of such property. This will enable sanitary authorities to buy it and to deal with it at such prices as will be consistent with justice to the poor and to the taxpayers as well as to the owners. Legislation in this direction will do little good if it is not accompanied by other legislation that will help the poor to save themselves. Society and religious bodies are becoming alive to their own risks and responsibilities in this matter. Society is like an organism: "if one member suffer, all the members suffer with it." We cannot divest ourselves of interest in slum-life by the exercise of any amount of selfishness. No luxury of the upper ranks of Society will save them in the long run from the dangers arising from the condition of misery and squalor of the poverty-stricken. Still, men must work out their own salvation. The poor must be helped, but they must help themselves. It seems monstrous that a working man should have to spend a third or a fourth of his wages in house-rent for one or two rooms. But it is equally monstrous that he, sometimes assisted by his wife, should spend the same proportion in beer or spirits. This regrettable fact is partly attributable to the very discomfort of his domestic conditions; but the tendency nowadays is to flatter the working man by assigning all his intemperance to his misfortune and none to his fault. This is another extreme. What is wanted is a little common-sense all round, including some wholesome legislation that will discourage drunkenness and divert to better uses some of the £162,000,000 spent yearly in cultivating it. Canon MOORE EDE said at the Church Congress that what is wanted is not so much to build houses as to raise the standard of those who lived in them. The Mayor of Newcastle, too, made a very terse remark—namely, that well-to-do artisans may be left to take care of themselves. They are as capable of doing so as any other class of the community. The State and sanitary authorities have enough to do in catering for the really poor and this must be done without harm to their self-dependence and self-respect. Such problems as those which we have indicated above are most urgent and yet most difficult, and not the least satisfactory bearing of the ending of the war in South Africa is that it may enable proper attention to be given to their solution.

A RECENTLY issued Parliamentary paper supplies us with information upon certain points of interest in connexion with the working of the Inebriates Act of 1898, and serves to remind us that the House of Commons which has been dissolved did two years ago pass a small Act dealing with one of the phases of the great question of the prevention of drunkenness in this country. Under this Act habitual drunkards convicted on indictment of crimes committed through "drink" and serious enough to warrant imprisonment can be sent to a State inebriate reformatory or to any certified inebriate reformatory willing to receive them instead of being consigned to penal servitude or hard labour. The return before us, however, informs us authoritatively that "no State reformatories have been instituted or are to be instituted," so that criminal drunkards of the more serious type are left to undergo purely penal treatment unless there is a reformatory voluntarily instituted by charitable individuals or by public local bodies willing to receive them. This omission of the Government to aid in giving effect to a salutary measure passed during its tenure of office can hardly be due to the ample accommodation which it found in course of being provided from other sources. It is a matter of notoriety that there has been considerable difficulty in finding accommodation for those habitual drunkards who should have been sent to certified reformatories after repeated convictions before magistrates for minor offences, and it is in consequence of this known difficulty that the number of convictions under the Act figuring in the report before us does not enable us in any way to estimate its possible future usefulness. We learn, however, from the same document that a number of reformatories are promised and that various localities propose to contribute to them or to others, the rate of payment apparently deemed sufficient being £1000 for the right to seven beds, with an additional weekly charge of 3s. 6d. for each case taken in. As this gives about 6s. per head per week for the board, lodging, supervision, medical attendance, and all else that is necessary for each inebriate under treatment, assuming that the subscribing locality makes full use of its rights, it is to be presumed that private benevolence will still have to help largely in the charitable work of reforming the drunkard. It is not, however, to past measures but to the possibility of future legislation that we should turn our eyes with a general election proceeding and with the promises of future members of a reorganised Cabinet published broadcast in their electioneering addresses and the reports of their speeches. We have already on two occasions[1] expressed our opinion that there rests a duty upon those responsible for the government of the country to give effect on an early occasion to the work of the Royal Commission which, under the presidency of Lord PEEL, spent three years in inquiring into the administration and operation of the laws relating to the sale of intoxicating liquors.

There is every probability that the Unionist party will return to office with a majority strong enough to enable it, independently *alike of those interested in the liquor traffic and of* its extreme opponents, to bring in and pass a thorough and effective measure of reform for the benefit of the whole community. Such a measure would hand down to posterity the names of those responsible for it adorned with a fame as lasting and as honourable as that earned by the successful and courageous conduct of an arduous and memorable war. There is, however, nothing in the addresses and speeches to which we have alluded to indicate that such a measure is contemplated, and the omission is ominous. That such an omission should be made out of deference to the wishes and voting powers of those engaged in a trade the abuses and not the usefulness of which it is desired to check is not to the credit of honourable politicians. The Unionist party occupies a position strong enough to enable it to avow and to carry out any intentions that it may have, and any want of courage shown either now or hereafter is likely to be long remembered by the enemies of those who exhibit it, while it is not likely to be forgotten even by their friends.

Annotations.

"Ne quid nimis."

THE HUXLEY LECTURE.

ON page 985 will be found the full text of the Huxley Lecture on Early Researches Leading up to the Antiseptic System of Surgery delivered by Lord Lister on Oct. 2nd at the opening of the winter session of Charing-cross Hospital Medical School. The proceedings took place in St. Martin's Town Hall, not far from the hospital, Mr. J. H. Morgan, the treasurer of the school, being in the chair. This lectureship was founded after the death of Professor Huxley out of a sum raised by the Medical School and its friends to commemorate the fact that Huxley received the whole of his medical education at Charing-cross Hospital. The lecture is a biennial one and Lord Lister's is the third of the series, the first having been delivered by Sir Michael Foster in October, 1896, and the second by Professor Virchow in October, 1898. It will, therefore, be seen that the Charing-cross Hospital Medical School has so far been singularly fortunate in being able to have representative men, pre-eminent in their several departments, as the speakers on these occasions. At the conclusion of the lecture a vote of thanks to Lord Lister was proposed by Dr. T. H. Green, and seconded by the Rev. Prebendary J. F. Kitto. In acknowledging the vote of thanks Lord Lister expressed the pleasure it gave him, now that he had retired from surgical practice, to be again speaking among colleagues.

FOOD PRESERVATIVES COMMITTEE.

THE members of the Food Preservatives Committee, Dr. Timbrell Bulstrode and Dr. F. W. Tunnicliffe, and Mr. Charles J. Huddart, its secretary, who proceeded last month to Ireland for the purpose of investigating the dairying industry of that country in relation to the use of chemical preservatives have now returned to town. The inquiries which they made embraced the city of Dublin and the surrounding district anc the great butter-making centres in the south and west o Ireland. In the north, time sufficed only for a visit to the county of Cavan, but in that county, as well as in those which were visited in the south and west, large tracts o country were traversed and detailed inspection was made of farms and farm premises and of the several operations which precede the actual despatch of milk t the large creameries and of butter to the markets anc factories. The processes of manufacture at creameries anc butter factories, as well as at bacon and margarine factories also engaged the attention of the Committee at one anc another place. In Dublin itself, not only were the official of the *Government departments interviewed*, but the Committee had the advantage of repeated conferences with Si Charles A. Cameron, the medical officer of health of Dublin and with his colleagues. The mass of information acquired a the result both of the visit paid to the continent (especiall to Denmark) and of the visit to Ireland just concluded wil need collation and summarising with a view to the presentation to the whole Committee of reports on those results which reports will need very careful consideration before th Committee proceed to draw up their report upon the evidenc before them.

RAILWAY MISMANAGEMENT.

EVERY few months, probably whenever the exigencies o space permit the editor to insert them, the columns of th *Times* are invaded by a score of letters complaining of th scandalous discomfort and unpunctuality. of the Englis southern railway companies. That recurrent period ha apparently again come round and the columns of our contemporary have borne their usual crop of correspondenc on this subject. We ourselves are not, of course, concerned directly with problems of railway management but all matters which touch upon questions of hygien concern us, and some of the defects of the administration and management of the railway lines which the letter in the *Times* reveal have a distinct bearing upon healt and therefore call for notice in our columns. Whereve there is dirt there is the possibility of disease, and dirty condition of the carriages calls for the stronges reprobation. Wherever there is over-crowding, even th temporary over-crowding of a railway compartment, ther is the possibility of danger to health, and the habitua over-crowding of trains into and out of London at certai hours of the day on all the southern lines, and unhappil on some of the northern lines also, is a matter callin earnestly for attention. Nor is the question of th gross unpunctuality which has prevailed for years on th southern lines without importance from the purely medica and hygienic standpoint. Anything which tends t enable the Londoner, and, to a less degree, the worke in all our great towns, to live away from his worl to pass every night at least in the purer air of th *country*, is advantageous to health. On the other han anything which tends to discourage the worker in tow from living in the country and obtaining his dail supply of fresh and unexhausted air is greatly t be deprecated, and it cannot be doubted that th habitual unpunctuality of the train service on the lines south of the Thames, together with the habitual overcrowding of the compartments during the busy hours of the day, constitute a serious hindrance to the growth of the practice which has grown up among business men of having their houses in the country. If the merchant, or the banker, or the professional man can leave his house in Kent, Surrey, or Sussex at a fixed hour each day certain of arriving in London without discomfort at the hour at which he is timed to arrive, and if he can leave London in the evening with the same certainty of reaching home without discomfort or unpunctuality, no arrangement would be more satisfactory for him alike from the point of view of health and of enjoyment. If, however, living in the country means for the London man of business two journeys in over-crowded compartments by trains which may arrive anywhere between 15 and 45 minutes after time, with all the rush and hurry and irritation, not to speak of possible pecuniary loss, which such delays mean, it is not astonishing if he comes to the conclusion that country air and country enjoyment may be purchased too dear and falls back upon a house in Chelsea or South Kensington. It must not be imagined because we have spoken in the main of railways in and out of London that this question is of importance in London alone. The same evils, though we are happy to believe in a less extreme degree, prevail on the railways to and from the other great towns of England where there is any considerable body of business men living in the surrounding districts. The difficulty of coping with this local traffic is, of course, very great, but it is not beyond the power of care and money to meet it successfully. The cost would no doubt be considerable. All great evils which have been permitted to grow till they have reached unendurable proportions are apt to require drastic and costly remedies. But that is not a reason for permitting the managers of our railways to shirk them altogether. Indeed, in the case of railways the existence of the evil in its present magnitude is in itself *sufficient condemnation of their administration.*

---

BUILDING BY-LAWS IN CREWE.

ALTHOUGH a quarter of a century has elapsed since it became incumbent upon local sanitary authorities to appoint a medical officer of health, there are still some members of these bodies who are ignorant of that official's duties and who appear to be only too anxious to minimise his influence. This indifference to the well-being of those whose interests they are supposed to serve is usually to be found in small rural districts where the evils resulting from inattention to hygienic laws are often counteracted by an abundance of pure air and by the simple habits of life of the inhabitants. In a large progressive town such as Crewe has of late years shown itself to be we should have expected to find more enlightenment, but to judge from a more or less acrimonious newspaper correspondence that has lately been passing between an alderman of the borough and the former medical officer of health our expectation would be vain. In his last annual report upon the sanitary condition of Crewe Dr. Meredith Young referred to the unsatisfactory manner in which some of the building by-laws were being carried out, upon which Alderman Briggs questioned the desirability of the medical officer of health interfering with the erection of new buildings or with the enforcement of the building by-laws. The particular by-law which Dr. Young was anxious to have more rigidly enforced referred to the concreting of the sites of dwelling-houses, and as Crewe is situated upon a bed of stiff clay it is surprising that any person should object to his recommendation. That a medical officer of health does not exceed his duty in calling attention to breaches of building by-laws is made clear in a communication to Dr Young from Dr. Franklin Parsons, assistant medical officer to the Local Government Board, in which he says that By-law No. 10 in Model Series 4, requiring a concrete layer under floors of houses, is made under the powers of Section 157 (2) Public Health Act, 1875, as one "with respect to the foundations of new buildings for the purposes of health." Article 18 (5) of the Local Government Board General Order of March, 1891, with respect to the duties of the medical officer of health, prescribes that "he shall advise the sanitary authority on any question relating to health involved in the framing and subsequent working of such by-laws and regulations as they may have power to make." Clearly, therefore, says Dr. Parsons, a medical officer of health is right to call attention (of course in temperate and judicious language) to conditions injurious or dangerous to health which are allowed to come into existence owing to failure to carry out the by-laws.

TREATMENT OF THE INSANE IN THE EAST.

ON August 6th there was opened on one of the lower slopes of Mount Lebanon, Syria, near to the carriage road from Beyrout to Damascus, a newly-built hospital for the care of lunatics. It has been founded by Mr. Theophilus Waldmeier, a veteran missionary in Abyssinia and Syria, and consists of a central administration block and two pavilions, for male and female patients respectively, accommodating 20 of each sex. 17 patients are already under care. A considerable area of land and gardens for the growth of wheat, olives, and other fruit surrounds the houses. Dr. Wolff, from the Munsterlingen Asylum, Switzerland, is the medical superintendent. This is the first organised lunatic hospital in Syria and it has in consequence attracted much attention, the need for such institutions in the East being great. It will probably be dependent upon support from Europe for a good many years. Dr. Percy Smith is the chairman of the committee in London, which includes amongst others Dr Robert Jones of Claybury and Dr. Bedford Pierce of York; Sir R. Tangye acts as treasurer.

GANGRENE OF THE INTESTINE FROM PORTAL THROMBOSIS.

AT the meeting of the Société Médicale des Hôpitaux de Paris on July 13th M. Edgard Hirtz and M. M. O. Josué read an important paper on this rare condition. When the mesenteric veins are obliterated as a result of portal thrombosis profound alterations occur in the intestine—sanguineou infiltration and *necrobiosis—which may be rapidly* fatal. The following case is an example. A woman, aged 33 years, noticed that her abdomen was enlarging. The increase in size was of sudden onset and at first took place rapidly and then more slowly. About the ninth day paroxysmal pains in the dorsal and lumbar regions appeared. The patient rapidly became weaker and diarrhœa (but not melæna) occurred. At the end of three weeks when she was admitted into the hospital she was very feeble and the abdomen was greatly enlarged. In the distended abdominal wall a collateral venous circulation was well *developed; round the umbilicus* was a network of veins in communication with the thoracic veins. There was much ascites The liver appeared to be of normal size; the spleen was enlarged. The lower limbs were œdematous. The jugular veins were distended. On the third day after admission the patient vomited twice or thrice and complained of acute abdominal pain. The features became drawn, the eyes sunken, and the nose pinched—in short, the *facies péritoneal* was present. During the night she was delirious and *on the next day* comatose. On the following day she died. At the necropsy a large quantity of serous fluid was found in the abdomen. At its middle for a distance of 20 inches the small intestine was of a red, enabling the Board to enforce upon a defaulting local authority the performance of its statutory duties, but it is certainly a question worthy of serious consideration whether the putting in force of the powers of the Board in one or two instances would not have a salutary effect upon other authorities who are exhibiting a spirit of indifference to their responsibilities.

ALCOHOL AND THE TROOPS RETURNED FROM THE WAR.

IN our issue of July 28th (p. 273) we drew attention to the desirability that the welcome offered to those who have fought and bled for their country, and we might add for us who have stayed at home, should not include the treating of them with an overplus of alcoholic drinks. We are induced to return to this subject owing to the announcement that the City of London Imperial Volunteers are expected home about the beginning of November. Some will be convalescent from wounds or sickness or possibly from both. Of the warmth of their reception there can be no doubt and it is fitting that they should be greeted with gratitude as well as with joy. They are the first volunteers as distinguished from regulars to serve in the fighting line who have left these islands; they have by all accounts seen plenty of fighting and have borne themselves nobly. Their home-coming, therefore, should be marked by a welcome which, although hearty, should be commensurate in dignity with the serious work which they have so well carried out. For these reasons we would beg enthusiastic friends and countrymen not to mar the return of these or of any troops by temptation to over-indulgence.

THE SMOKE NUISANCE.

OUR remarks last week about the recrudescence of the smoke nuisance promise to stir up public opinion with good effect on the desirability of suppressing this intolerable evil. The newspapers in general expressed the opinion that we "waxed somewhat strongly" on the subject, but we do not admit that our words were too emphatic. The *Westminster Gazette* in quoting our article added the stale remark that "it is unfortunately easier to point out the evil than to suggest a permanent remedy." This remark hardly needs reply from us, since Sir William Richmond promptly cleared the mind of the writer of it on this point. Sir William Richmond's answer was as follows :—

> It is cheaper to consume smoke than to allow it to pass into the atmosphere. Smoke is wasted fuel. At a comparatively small cost all factories, electric lighting stations, &c., can be provided with smoke-consuming apparatus. This being the case the public has only to demand a clear atmosphere—anyhow as far as the smoke from factories, steamers, and railway engines is concerned—and they will get it. The vestries and the L.C.C. do not enforce the law against smoke partly on account of apathy, but chiefly because in those bodies there are many smoke-makers, or friends of such.

Sir William Richmond wrote a similar letter in the *Daily Graphic*, Oct. 3rd, *à propos* of our remarks. As a reference to our correspondence columns this week will show, Sir William Richmond has also addressed us upon the subject. We most sincerely hope that his appeal will receive the support of all who are interested in keeping "a clean sky" and stopping once and for all the vestries and other authorities from "making it dirty." It is sheer nonsense to say that smoke cannot be prevented. The fact is the question is not seriously considered. It has been demonstrated again and again that properly constructed boiler furnaces when properly fixed need not smoke. The best example that we know of in this connexion is in the case of Nottingham, where black smoke was practically abolished because the nuisance proved to be injurious to the lace produced there. This is a complete answer to the observation that "it is unfortunately easier to point out the evil than to suggest a permanent remedy." It is nothing of the kind. More than that, when preventive measures are taken, it is a source of added revenue. It is just as important, in our opinion, that our public health authorities should see that the atmosphere which we breathe is untainted as that the water which we drink is unpolluted and the food which we eat is unadulterated.

THE UNIVERSITY OF LONDON.

THE first meeting of the Senate of the University of London will take place on Oct. 24th and the members of the various bodies appointed to serve thereon must be soon elected. The Royal College of Physicians of London has appointed Dr. P. H. Pye-Smith and Dr. W. H. Allchin, and the Royal College of Surgeons of England Mr. H. G. Howse and Mr. A. Pearce Gould as their representatives. These gentlemen have the advantage of being old graduates of the University and are well versed in the movements for its conversion into a teaching university and the opposition to such a change. On Oct. 9th, at 5 P.M., a meeting of Convocation will be held at the University new building at South Kensington, in the East Conference Hall, for the appointment of the members to serve on the Senate under the statutes made by the Commissioners. The registered graduates in medicine and in surgery are urged to elect Dr. Thomas Barlow and Dr. J. Frank Payne on the one hand, or Dr. S. Ringer and Mr. Quarry Silcock on the other, but two only can be elected. Dr. Barlow and Dr. Payne are frankly in accord with the views put forward by us for the establishment of a real teaching university in London, whilst Dr. Ringer and Mr. Silcock have the strong support of the so-called Graduates' Association, urging strongly that the existing work of the University is to be kept up as far as possible as it now is. The question of external students in arts and science, on which so much stress is laid in the circular of the association, does not much concern the medical student, but a re-organisation of examinations, so that he may not be examined twice or thrice in the same subject, is a far more necessary reform for the proper teaching of medical science and practice.

THE HARD CASE OF THE ROYAL LONDON OPHTHALMIC HOSPITAL.

WE have already[1] expressed our sympathy with the movement which has for its object the exemption of hospitals and similar charitable institutions from the payment of local rates, and a case has just occurred which shows with painful clearness how seriously this burden may affect the financial position of a hospital. The Governors of the Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City-road, E.C., received a summons for non-payment of rates amounting to £324, and although the secretary explained at the hearing of the case that it was impossible for so large a sum to be forthcoming at present, the court held that it could do no more than make an order for payment in 14 days. This claim seems to be particularly hard in view of the fact that the new building has only been occupied for one year, and during that time the hospital has actually paid £540 in rates. Besides suffering like all other charities by the diversion of subscriptions to the various war funds and the Indian Famine Fund, this hospital has to meet an increase of expenditure consequent upon the occupation of larger buildings in the way of an increase in wages and in the cost of lighting and heating. It also has now to pay £1210 a year ground-rent, whereas the old property at Moorfields was freehold, and its rates are now £870 as against £50 at Moorfields The sale of the old site will pay for the erection and equipment of the new building, but the committee earnestly appeal for new subscriptions to meet the increased cost of maintenance under the present improved conditions

KERATOLYSIS OR SKIN-SHEDDING

IN the *Journal of the American Medical Association* of Sept 1st Dr R M Stone has recorded a case of this curious affection which is analogous to the moulting of birds The subject was a strong, healthy man, aged 50 years, who shed his skin every year He was born in May, 1849, and shed his skin in the following July, and since then every summer In 1893 1899, and 1900 he shed his skin twice at intervals of a month The period of shedding is ushered in by a feeling of malaise and chilliness and is followed by fever with a temperature as high as 103° F The skin of the body desquamates, but that of the palms, elbows buttocks, penis and scrotum, knee caps, and feet comes off in a mass The hair of the head, eyebrows, and moustache falls The patient does not become bald, but the hair falls little by little, as after typhoid fever The nails also participate in the shedding During the period of shedding the patient is able to work When the skin begins to be shed perspiration ceases and the epidermis becomes raised and hard so that when struck it gives off a sound like that of celluloid The patient's family history is good and no relative has been similarly affected

UP to the time of going to press the following medical candidates have been re elected Members of Parliament —John Dillon, L R C S Irel (Mayo East), Sir M Foster, M D Lond, K C B (London University), C K D Tanner, M D, M Ch R U I (Mid Cork), and Sir J Batty Tuke, M D Edin (Edinburgh and St Andrews Universities)

THE opening address at the London School of Tropical Medicine was delivered on the evening of Oct 3rd by Sir William McGregor, K C M G, M D, the subject being Some Problems in Tropical Medicine The address will appear in full in THE LANCET next week

THE First Hunterian Lecture will be delivered before the Hunterian Society at the London Institution, E C by Dr Norman Moore on Oct 10th at 8 30 P M The subject will be the Clinical Study of Heart Disease Members of the medical profession are invited to attend,

WE have received the report of the Commissioners in Lunacy for England and Wales for the year 1899 We hope shortly to publish an extended notice of the report

A REUTER'S telegram of Sept 30th from Brisbane states that a case of plague has been reported at Charters Towers Queensland

WE are informed that a meeting of the Penal Cases Committee of the General Medical Council was held on Oct 2nd.

BRITISH DENTAL ASSOCIATION — The annual general meeting of the South Wales and Monmouthshire branch of the British Dental Association was held at Newport on Sept 27th Mr J C Oliver in an interesting address said that the point as to whether it was legal for an unregistered person to practise dentistry for profit had never been decided by the law courts Mr Graham White was elected president for the ensuing year It was decided to hold the next annual meeting at Cardiff

THE FERRUGINOUS BATHS OF SHANKLIN SPA

SHANKLIN in the Isle of Wight has long possessed a ferruginous spring of some merit, but like so many other meritorious natural mineral waters in this country its value has not been widely recognised In spite of representations to the contrary English people still visit the various spas of the continent, whatever may be the advantages which may be had at similar places in this country Fashion is doubtless the chief factor which has hitherto been unfavourable to enterprise in regard to the development of English spas Yet if a list of the natural springs of Great Britain be consulted it will be found that almost all kinds of mineral waters occur in this country We have thermal waters at Bath, sulphur waters at Harrogate and Llanwrtyd in Wales, and saline springs and barium springs in Wales not to speak of the chalybeate springs at Tunbridge Wells, Brighton, and elsewhere In some instances, of course great effort has been made to equip these places on a scale similar to Homburg, Wiesbaden, and Schwalbach on the continent, but our home resorts do not possess the renown of the foreign spas Individual enterprise has done what it could but patronage has failed In particular however, it would appear that attention has never been seriously directed in this country towards utilising ferruginous water for bathing purposes, at least we know of no installation of this sort, although as is well known, there are several celebrated chalybeate waters abroad as at Schwalbach and Homburg in Germany and Spa in Belgium, where natural ferruginous water is heated in a specially constructed bath for immersion purposes These waters are chiefly employed for cases of anæmia and general debility

Although in England chalybeate waters are fairly abundant no attempts have been made to utilise them on any scale for bathing purposes or it may be that the yield of ferruginous water is not consistent with the erection of baths on any important scale At Shanklin, however, there is an abundant supply of pure ferruginous water which if circumstances needed could be further developed Hitherto the ferruginous waters at Shanklin have been practically allowed to run to waste but arrangements have recently been made for the storage of this water in view of its adaptation to bathing purposes on a plan exactly coincident with that adopted at the "Stahlbrunnen" abroad, and the promoters of the scheme have gone the right way to work, for they have wisely studied the method in vogue at the continental resorts before deciding to embark upon an installation of ferruginous baths at this very accessible and healthy seaside resort The initial difficulty is to heat up cold ferruginous water to the necessary temperature for a bath without disturbing the natural state of its mineral and gaseous ingredients As a rule the ferruginous waters of this country contain protocarbonate of iron held in solution by the carbonic acid of the water As soon as such waters reach the surface rapid oxidation of the iron ensues red ferric oxide deposits, and carbonic acid gas is set free This disintegration is hastened when the water is heated and an unsightly mixture is presented to the bather, besides which at that point it could not be said that he was taking a bath in the water in exactly the same condition as it flows from his natural source The promoters of the Royal Shanklin Spa, as we have said, did wisely by gaining the experience of others with regard to the elucidation of this problem and they appointed delegates to visit the ferruginous spas abroad with a view of adopting the same successful methods at Shanklin The work of survey being completed the work of construction was executed with commendable expedition and there now exists a system of ferruginous baths at Shanklin identical with those at Homburg, Spa Schwalbach and elsewhere It is true that at present the installation is on a small scale, but the appointments are excellent and such as meet the special requirements of patients in regard both to

con

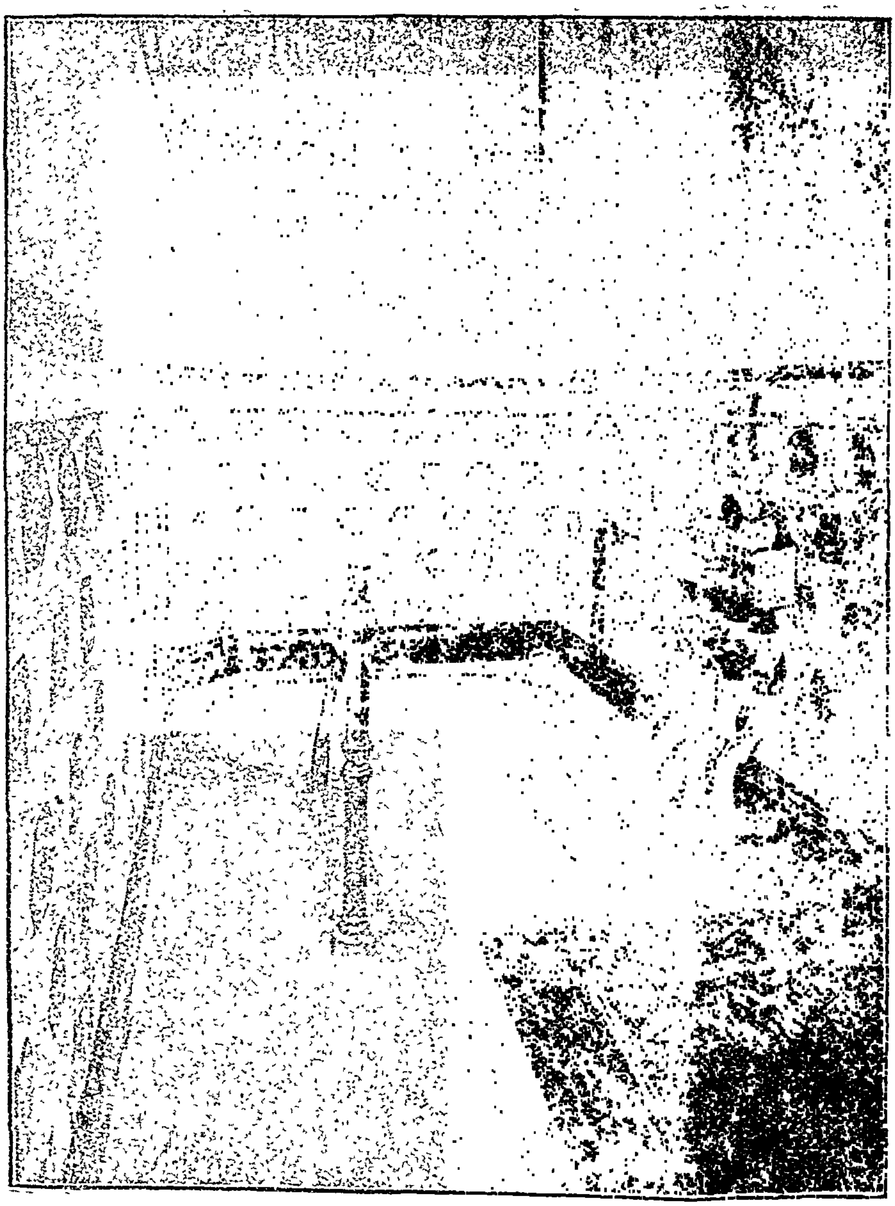
whi

by

it is stated in the volume dealing with the geology of the Isle of Wight (by Henry William Bristow, F.R.S., F.G.S.: London; Eyre and Spottiswoode) that chalybeate water sisues from these strata. "The spring known as Shanklin Chalybeate Spa was first noticed by Dr. Fraser, physician to Charles II."

It is interesting to compare the analysis of Shanklin Spa water with the analyses of other ferruginous waters both at home and abroad. The Tunbridge Wells chalybeate water, according to published analyses, contains one grain of carbonate of iron per gallon and a total solid contents of eight grains per gallon. Brighton chalybeate water contains eight grains of carbonate of iron per gallon associated, however, with 92 grains of other salts. The gallon, but this is associated with a very large quantity of saline constituents, chiefly chloride of sodium, the total of which amounts to from 600 to 1000 grains per gallon. The Kreuznach springs are similarly composed containing a little over three grains of carbonate of iron per gallon. The Schwalbach waters contain from four to eight and a half grains of carbonate of iron per gallon with from 27 to 90 grains of total mineral ingredients. The Stahlbrunnen at Schwalbach contain as much as 5·85 grains of carbonate of iron with 32 grains of total solid constituents. The waters of Spa in Belgium contain 3·41 grains of carbonate of iron per gallon with a total solid contents of 35 grains per gallon. Many other continental springs could be quoted, but these are sufficient for the purpose as being the most

FIG. 3.



One of the deep baths.

thermal waters of Bath, according to THE LANCET analyses, contain nearly two grains of carbonate of iron per gallon with 140 grains of other salts. Most of the other ferruginous springs at home contain iron in the form of ferric sulphate which is generally associated with excessive quantities of alum which render them very astringent. Such are, for instance, the Sandrock spring in the Isle of Wight, the chalybeate spring at Hastings, and various other springs in Derbyshire, Bedford, Bucks, and elsewhere. As regards continental mineral waters the Homburg Stahlbrunnen contain from 8·55 grains to 4·82 grains of carbonate of iron per important in regard to their application to balneological practice.

It will be seen that Shanklin Spa water compares very favourably with many of the [illegible] waters abroad: indeed, for some pu[illegible] certain advantages. It is not [illegible] is the most important const[illegible] water is on this account more palatable than the strong saline chalybeates abroad. It is also on the same account less "sticky" in the bath. The nature and in some particulars the amount of the mineral ingredients of Shanklin Spa water are was made for the presence of comparatively rare constituents, but with the exception of traces of lithium none were found. It is an advantage that Shanklin Spa water is free from alum and it is not accordingly very astringent. The iron is present entirely in the unoxidised state—the protocarbonate of iron formed in the Blaud pill.

Though at present the installation of ferruginous and other baths at Shanklin Spa is only on a small scale, the fact that an excellent start has been made, and on lines fully in accordance with balneological practice abroad, deserves to be recognised. The enterprise is one worthy of all encouragement, and there is no reason why the experience ultimately gained at the Shanklin baths should not yield evidence that this admittedly valuable method of treatment in hydro-therapeutics may be carried on just as efficiently and with equal satisfaction to the patient in this country as at health resorts abroad. Ferruginous baths are said to be of conspicuous value in debilitated conditions. The advantages of a health resort being easily accessible at which a course of treatment by baths may be pursued and where the action of the sea air is invigorating, are undeniable. As is well known, Shanklin is situated on a bracing coast and in addition to this very important source of benefit to persons who are recruiting health it now presents a system of medicinal baths of which the equipments and appointments are not less satisfactory than are those of foreign watering-places.

CHANGES IN THE MEDICAL SCHOOLS.

St. George's Hospital.—The following changes have taken place in the staff of the hospital and school. The term of office of Mr. Warrington Haward, senior surgeon, having expired Mr. W. H. Bennett becomes senior surgeon. Mr. Marmaduke Sheild has been appointed surgeon and Mr. Herbert Stringfellow Pendlebury assistant surgeon to the hospital. Dr. Fenton has been appointed curator of the museum, vice Dr. Lazarus-Barlow, who has become pathologist to the Westminster Hospital. Dr. Dickson has been appointed medical registrar, vice Dr. Fenton. Dr. Menzies has been appointed senior anæsthetist, vice Dr. Dickson, and Dr. Llewelyn Powell has been appointed junior anæsthetist, vice Dr. Menzies. Dr. Penrose has been appointed joint lecturer (with Dr. Isambard Owen) in the principles and practice of medicine, vice Dr. Ewart, resigned Mr. G. R. Turner has been appointed joint lecturer (with Mr. Clinton Dent) in the principles and practice of surgery, vice Mr. W. H. Bennett, resigned. Dr. Cyril Ogle has been appointed lecturer in materia medica and therapeutics, vice Dr. Penrose. Mr. Francis Jaffrey has been appointed lecturer in anatomy, vice Mr. Turner. Dr. J. Howell Evans has been appointed demonstrator in anatomy. Mr. Clinton Dent has been appointed treasurer of the medical school, vice Mr. Warrington Haward.

King's College, London.—The changes during the past year have been the retirement of Professor I. Burney Yeo, the succession to the chair of Medicine of Professor Tirard, and the appointment of Dr. F. W. Tunnicliffe to the chair of Materia Medica and Pharmacology; also additions to the hospital staff of Mr. Leslie and Mr. Legg and Dr. Hugh Playfair as medical, surgical, and obstetrical registrars and tutors respectively.

London Hospital Medical College.—On the medical staff the death of Dr. Charlewood Turner has led to the appointment of Dr. Percy Kidd in his place as physician; Dr. Robert Hutchison has been appointed assistant physician. On the surgical staff Mr. H. L. Barnard has been appointed as an additional assistant surgeon; Mr. Farmer succeeds Mr. Cunningham as dental surgeon. In the College Mr. A Keith has been appointed joint lecturer on anatomy, still retaining his senior demonstratorship on anatomy. Dr. Robert Hutchison has been appointed lecturer on Chemical Physiology and Foods and Dietetics, and Dr. J. J. R

Middlesex Hospital.—Dr. Sidney Coupland and Sir R. Douglas Powell, Bart., have been appointed consulting physicians; Dr. C. Y. Biss has resigned; Dr. W. Pasteur has been appointed physician; Dr. F. J. Wethered and Dr. H. C. Thomson have been appointed assistant physicians; Mr. W. Hern has been appointed dental surgeon, Mr. W. S. Nowell assistant dental surgeon, Dr. H. P. Noble assistant anæsthetist, Mr. C J. Baker casualty medical officer, Dr. J. T. Wills casualty surgical officer, Dr. W. Pasteur lecturer in medicine, Mr. A. Pearce Gould lecturer in surgery, Dr. W. E. Wynter lecturer in practical medicine, Mr. J. Murray lecturer in practical surgery, Dr. A. M. Kellas lecturer in chemistry, vice Dr. Plimpton, deceased, and Mr. T. H. Kellock surgical tutor.

London (Royal Free Hospital) School of Medicine for Women.—Dr. Brodie has been appointed lecturer on physiology, vice Dr. Starling, resigned; Miss Ellaby, M.D Paris, has been appointed lecturer on ophthalmic surgery, vice Mr. J. G. Mackinlay, deceased; and Dr. Phear has been appointed assistant physician at the Royal Free Hospital, vice Dr. J. Fawcett, resigned.

Owens College, Manchester.—The council of the Owens College has appointed Mr. F. A. Southam to be professor of clinical surgery in place of Mr. W. Whitehead, who has resigned. Mr. G. A. Wright has been appointed professor of systematic surgery in place of the late Mr. Jones. These appointments are subject to confirmation by the Court of Governors at their meeting in October next. Mr. W. Thorburn has also been appointed lecturer on operative surgery and Mr. Joseph Collier has been appointed lecturer on practical surgery.

University College, Liverpool.—Professor Lodge has resigned the chair of Physics on undertaking the Principalship of the University of Birmingham and Dr. E. P. Manby has resigned the post of assistant *lecturer in hygiene and is* replaced by Dr. Mussen. Dr. Willett has given up the post of obstetric assistant. Dr. N. E. Roberts has become lecturer on infectious diseases and vaccination. Dr. Buchanan has been made assistant lecturer in forensic medicine. Dr. J. S. Macdonald has been made assistant lecturer and senior demonstrator in physiology. Dr. Balfour Stewart has been appointed research assistant in bacteriology.

Anderson's College Medical School.—Dr. J. G. Connal has been appointed to the lectureship in Diseases of the Ear, in room of Dr. Erskine Professor Carstairs Douglas has been appointed to the chair of Medical Jurisprudence in room of Professor R. M. Buchan. Dr. Carroll has resigned the lectureship in Public Health, but no new appointment has yet been made.

St. Mungo's College, Glasgow.—Dr. McPhail has been appointed professor of anatomy, vice Mr. Kent.

THE WAR IN SOUTH AFRICA.

THE regular warfare in South Africa came to an end with the flight of Mr. Kruger into Portuguese territory and the occupation of Komati Poort by our troops, as we had long ago surmised would be the case. It now only remains to deal with the dispersed bands of the enemy who will no doubt continue to provide work for some time to come for the army of occupation and for the 12,000 police to be raised in the Transvaal Colony and Orange River Colony under the command of General Baden-Powell. There will nevertheless be a good deal to occupy the serious attention of the newly elected Parliament in connexion with the wars going on elsewhere, as in China and Ashanti, and the promised reorganisation of our military forces and army reform. As to army reform, not only has the nation desired it, but the appointment of Lord Roberts as the new commander-in-chief will ensure it. When the Royal Commission have finished their investigations and made their report on the hospitals in South Africa we shall see how far the medical services are likely to be involved in the general scheme of army reform. For the present the nation is engaged in the turmoil and throes of a general election. There is much, however—of army medical interest at the present moment apart altogether from matters of imperial, domestic, and foreign politics and questions of a purely military nature.

We may deal, first of all, with the speech of Mr. W. Burdett-Coutts to his constituents at the Westminster town-hall on Sept. 29th, a printed report of which we have read. It would be impossible to take up and consider all the points embodied in it; nor is this necessary, for even admitting a good deal of what he has put forward in vindication of his action we may nevertheless pass over much of his address as really irrelevant so far as we are concerned. We are not among those who have made accusations against him about want of patriotism, loyalty to party, and so forth. But assuming, for the sake of argument, that Mr. Burdett-Coutts's statements about the war hospitals were absolutely correct and neither exaggerated nor highly coloured, the question really was as to the causes of the sufferings of the sick and wounded which he described, whether these were unavoidable or not under the circumstances, and whether he had spared no pains to ascertain the true state of affairs before harrowing public feeling by the publication of his painfully realistic descriptions. There is no denying that the publication of his letter in the *Times* had a most painful effect, especially upon the relatives of those fighting in South Africa, and this feeling had an additional and bitter sting and became well-nigh intolerable when accompanied by a belief that the sufferings of the sick and wounded were the result of neglect and might have been prevented, instead of being unavoidable and attributable to the stress and strain of war. We have at present the opinion of Lord Roberts and his staff, who ought to know, on the one side, and that of Mr. Burdett-Coutts on the other; and when the report of the Royal Commission is published we shall, it is to be hoped, learn all the facts. What we have all along contended for is that Mr. Burdett-Coutts was not justified in publishing his letter until he had learned what the military authorities had to urge in explanation of the position and until he had made himself thoroughly acquainted with all the circumstances of the case. It is all very well to appeal now to the tribute which he paid to Lord Roberts's qualities as a soldier and as an eminently humane man. No one doubts them or simply seeks to shield himself from blame behind the authority of Lord Roberts's name, but as Lord Roberts was in supreme command and on the spot he was officially responsible for everything and, what is more, he manfully accepted that position, he courted inquiry, and he gave an emphatic expression of his own views on the matter. No one knew when the war commenced that instead of 50,000 troops 200,000 would be required and would be sent to South Africa, and it is wide of the mark, as far as the medical service is concerned, to make any capital out of the fact that the provision which would suffice for the one force would not suffice for the other. The sudden and deplorable outbreak of enteric fever was not foreseen. It followed the rapid march of the troops to Paardeberg and was probably attributable to their occupation of that most insanitary place and to the subsequent capture of the waterworks at Bloemfontein by the Boers. We see no reason for not adhering to the view which we entertained from the first, that transport was *the* difficulty in this war, which in almost every other respect, also, has been of an exceptionally difficult character. In point of fact we have been assured that no one who has not been in the country and taken part in the present war can realise what the difficulties were. We believe that, even apart from our position and advantages in respect of transport as a sea-power, there is no other nation, despite the shortcomings and mistakes that have been made, which could have accomplished what has been done in South Africa. As regards the alleged improvements that have taken place in the state of the hospitals since the publication of Mr. Burdett-Coutts's letter—which he attributes to the result of his disclosures—we would merely remark that it is not the first time that a *post hoc* has been confused with a *propter hoc*. He omits to say anything about the period of exceptional strain having in the meantime passed away and the extreme difficulties in regard to the transport and distribution of hospital stores and material having been overcome, and apparently regards these as factors of no importance.

The last War Office return issued shows the total casualties since the beginning of the war up to the end of last week, as follows:—

—	Officers.	Non-commissioned officers and men.
Killed in action	287	2,750
Died from wounds	86	825
Prisoners who have died in captivity	3	89
Died from disease	150	5,753
Accidental deaths	3	114
Total deaths in South Africa	529	9,531
Missing and prisoners (excluding those who have been recovered or have died in captivity)	7	812
Sent home as invalids	1,326	30,300
Total, South African Field Force ...	1,862	40,643
	42,505	
Total reduction of the military forces through war in South Africa.—		
Deaths in South Africa	529	9,531
Missing and prisoners	7	812
Invalids sent home who have died	4	193
Invalids sent home who have left the Service as unfit	—	873
	540	11,409
Total	11,949	

THE IMPERIAL YEOMANRY BASE HOSPITAL.

BY L. V. CARGILL, F.R.C.S.,

OPHTHALMIC SURGEON TO THE HOSPITAL.

There are 31 officers and 972 men to-day in hospital, 12 officers and 447 men belonging to the Imperial Yeomanry. Since the hospital started we have treated 200 officers and 3152 men, 1000 of whom have been Yeomanry.

The Hospitals Inquiry Commission visited us on August 30th. They arrived from Cape Town by their special train at 9 A.M. and after inspecting the camp and taking evidence proceeded north *en route* for Pretoria at 2 P.M.

As regards the medical cases in hospital they are still of a mild type and similar in character to those mentioned in the last letter. One of our orderlies who was on night duty in an enteric fever ward unfortunately contracted the disease some few weeks ago, and although the attack was of moderate severity perforation of the bowel ensued and he died from peritonitis. He was the first orderly whom we have lost from enteric fever, although others have had it.

The enteric fever wards are now being emptied and thoroughly cleansed and disinfected in turn. One of the orderlies who has been in bed for some months suffering from acute rheumatism and pericarditis is now convalescent. Dr. Washbourn has gone to Pretoria to visit the Branch Hospital, and during his absence Dr. Andrew Elliott will be senior physician. There has been no further case of measles contracted from the one case which we have had. In one or two cases of patients desquamating and giving a previous history of rash and sore-throat they have been admitted and at once isolated.

The work in the surgical wards has been heavier during the last two or three weeks than for some months past, and six marquees have had to be transferred from the medical to the surgical side to accommodate the patients sent down. Last week, in response to an urgent telegram from Lord Methuen, Mr. Ballance journeyed north to Mafeking to see in consultation Brigadier-General Little, commanding the 3rd Cavalry Brigade, who had been seriously wounded in the right hip by a soft-nosed bullet which had struck a metal cigarette-case that was in the patient's pocket at the time. A severe lacerated wound had resulted, the entry being three inches vertically below the anterior superior iliac spine and the exit a little below the posterior superior spine on the same side, the track being immediately adjacent to the hip-joint. The patient was brought down to Deelfontein in No. 5 Hospital Train, which was at Mafeking at the time, and the rest of the 96 patients, 40 per cent. of whom were wounded, were also detrained here. Brigadier-General Little is now progressing favourably and it is hoped that some movement in the hip-joint will eventually be retained. We have had rather a monopoly of the patients from Mafeking, as this is only the second occasion on which a hospital train has been up there. The first train went up shortly after the siege was raised and it brought down the sick and wounded among the besieged and from the relief column. The wounded in Mafeking at the present time are from the operations round Malmani, Zeernst, and Elands River. Mr. Hall-Edwards has thus been kept unusually busy in localising bullets and shell fragments in the x ray department.

Last week the first amputation occurred in the hospital since its commencement in March last and this speaks volumes for the efficiency of the modern antiseptic treatment of compound fractures and the merciful character of the Mauser bullet, a large number of compound comminuted fractures having been treated here. The case was one of severe compound fracture of both legs by the same bullet and Mr. Ashdowne amputated the right thigh in the lower third on account of spreading osteomyelitis in the bones of the leg which previous operations had failed to stop. The patient is now doing well and it is hoped that the fracture in the left leg will heal.

The first circumscribed traumatic aneurysm in this hospital was operated upon by Mr. Parker a few days ago. The case was one of a man who was shot in the left forearm by a Mauser bullet at a range of 100 yards. The bullet entered the back of the limb one and a half inches below the tip of the olecranon process and emerged on the flexor aspect after fracturing the ulna two inches below the bend of the elbow at the anterior border of the supinator longus. The posterior wound had closed, the anterior one was still open, and on Sept. 5th the patient suddenly lost three or four ounces of blood from it. There was a pulsatile swelling three inches in diameter on the anterior surface of the forearm just below the elbow. The radial pulse was strong; the ulna could not be felt. At the operation after turning out the clots an aperture was found in the ulnar artery about three quarters of an inch from the bifurcation of the brachial. The injured vessel was tied above and below the wound and the patient is now doing well The aneurysmal cavity extended between the bones of the forearm on each side of the interosseous membrane, in which there was a hole one inch in diameter, but by far the largest part of the tumour was situated on the anterior aspect of the membrane.

We have only had a few wounds from shrapnel bullets, but their lack of penetrating power is very marked as compared with small-bore missiles. Mr. Ballance had a very interesting case of a man in whom a shrapnel bullet entered the back at a quarter of an inch to the right of the middle line and on a level with the sixth dorsal spine. By means of the x rays it was localised under the sixth right rib in front, half an inch to the inner side of the mammary line, and from this position it was removed by resecting a portion of the rib, the bullet being partially imbedded in the surface of the lung. A shrapnel bullet has in another case been removed from the upper end of the left femur at the level of the junction of the neck and shaft. It had entered the outer aspect of the hip and penetrated the great trochanter. One shrapnel bullet entered the outer side of the left leg on a level with the tubercle of the tibia, the shell having burst 20 yards from the patient. The bullet had just enough energy left to perforate the head of the tibia horizontally and lodge under the skin over the inner tuberosity, whence it was removed by Mr. Parker.

A most interesting case of abscess of the brain resulting from a Mauser-bullet wound has been operated on in the hospital The man was shot on April 13th near Wepener, the bullet entering the forehead one inch vertically above the inner end of the right eyebrow and after traversing horizontally the right cerebral hemisphere it emerged in the occipital region two inches above and to the right of the external occipital protuberance along a line drawn from this point to the right parietal eminence. He was helped off his horse and taken to the hospital and from the time of receiving his wound had been completely paralysed in the left arm and leg. Three months later he was brought down to this hospital with wounds which had long since healed and was in a very drowsy condition with subnormal temperature and a pulse-rate of 54. The left arm and leg were absolutely paralysed but not anæsthetic; the left side of the face was partially paralysed. The knee-jerks were exaggerated; the urine and fæces were passed into the bed. Two days later the drowsiness had increased and external strabismus with dilatation of the pupil had developed in the right eye. I reported commencing optic neuritis on both sides, more marked on the right. Mr. Ballance then trephined over the lower part of the right Rolandic area and after puncturing the frontal and parietal lobes without success an abscess was tapped in the occipital lobe and from four to six drachms of thick yellow inodorous pus were evacuated. The bony aperture was enlarged posteriorly and a tube was inserted. Unfortunately, the patient died on the next day with a temperature of 104 4° F., never having recovered consciousness from the time of the operation. At the necropsy the abscess drained at the operation was seen to be situated in the centre of the right occipital lobe and the cavity was about one and a half inches in diameter. There were two other smaller abscesses which had been untouched by the operation—one in the upper and one in the lower part of the right parietal lobe near the surface of the brain. In the region of the genu of the right internal capsule a patch of white softening was found. There were no portions of bullet or clothing in the cerebral substance. In an agar tube inoculated at the operation a pure cultivation of the staphylococcus pyogenes aureus grew. Apparently the hemiplegia was due to direct destruction of the fibres of the internal capsule by the passage of the bullet and was not due to the pressure of the abscess.

Deelfontein, Sept. 10th.

SOME HOSPITALS IN SOUTH AFRICA.

(FROM ONE OF OUR CORRESPONDENTS.)

The distances in South Africa are so great and the difficulties just now of travelling are so enormous that it is impossible for any one man to visit all the various military hospitals in a short time, but some brief account of those existing in August may be interesting. No attempt in this communication will be made to describe the excellent work which has been done on the Natal side under the superintendence of that able organiser, Colonel T. J. Gallwey, R.A.M.C. Suffice it to say that after evacuating the sick and wounded through Newcastle and Durban by means of the Princess Christian and No. 1 Ambulance trains, and sending them home to England by troopships every fortnight, Colonel Gallwey proceeded to Pretoria a month ago for a special conference with Surgeon General W. D. Wilson, at which it was decided that in future the sick should be sent down by way of Durban instead of by the tedious route through the Orange River Colony to the Cape. This is now being done and it is an obvious improvement for the patients, for besides being much shorter the trains can travel at night without fear of being "held up" by De Wet.

Altogether 35 000 sick and wounded have passed through Cape Town since the beginning of the war; half of these have been invalided to England and the others have returned to duty in the field. Of this large number the mortality is only a little above 1 per cent., but this death-rate does not include those who died at sea or in hospitals in England after arrival there.

The Director-General of the Army Medical Service in London has despatched to the Cape 13 general hospitals, each equipped for 520 beds but elastic enough to spread to double their size; and without counting convalescent homes and small hospitals under 100 beds the general public have added eight auxiliary hospitals. The number of army medical officers in South Africa has been about 460, and their civilian brethren working under them have numbered a few more. If to these we add the civilians employed in auxiliary hospitals we arrive at a total of at least 1000 medical officers. The army has employed its junior officers—captains and lieutenants—in regimental work, with field hospitals, and with ambulance trains; while the seniors—colonels and majors—have been in command of general hospitals, have acted as registrars and secretaries, and have nominally been in charge of the three divisions into which most large hospitals are divided—surgical, medical, and enteric. In most places this system has worked uncommonly well, and the military officers, occupied with constant returns and army regulations, have been well content to leave the purely professional labours of the hospitals to the young civil surgeons, many of whom have quite recently held important posts as residents in London hospitals. Friction has only occurred on the very limited occasions when an unwise colonel, a generation older than the civilians, has attempted to impress on them the value of antiquated notions of nursing, medicine, hygiene, and surgery. In those cases where the principal medical officer of the hospital is a man who has succeeded in keeping abreast of the times in spite of the great difficulties which surround his department the civilian surgeons have been glad to learn from him not only military routine but the general treatment of disease. It must never be forgotten, too, that much of the success of the auxiliary hospitals has been due to the splendid work of the military commandants furnished to them by the Royal Army Medical Corps.

Cape Town and the Cape Colony.

In July Cape Town was in the midst of the rainy season and was determined not to forget it. Table Mountain was enveloped in mist, the rain fell all day, and the streets were often impassable from thick mud and ponds of water; but now the sun shines on the lovely mountain, mackintoshes and umbrellas have been put away, and the gardens and fields have burst out into a carpet of white arum lilies which grow like weeds. I took an early opportunity of visiting No. 5 General Hospital at Woodstock, which is within a mile of the Cape Town railway-station, because of the attacks lately made upon it. The first thing I was told by the medical officers in charge was that to the best of their knowledge the hospital had never been visited by Mr. Burdett-Coutts. I examined it very thoroughly and whatever its former condition may have been I could find nothing to criticise in the conduct of the hospital. Its site no one will attempt to defend, because it was condemned more than a year ago, but directly the war broke out Sir William Butler decided that even a condemned hospital must be used, as there was obviously no time to construct a new one. In this most practical men will think that he was justified. The obvious faults are that the old wooden huts harbour insects in the summer, as all wooden buildings in all hot countries are known to do, and that the huts are at the edge of the sea, exposed to the discomfort of the south-east wind when it rages and within full view of one of the city drains. The sight of drain-pipes does not make the smell of decomposing seaweed any the more agreeable, but there is no evidence that either medical or surgical cases have suffered in this hospital. Moreover, those to whom Mediterranean fever is well known assured me that they had seen no cases of it at Woodstock. This is interesting, because there are present all the predisposing factors—southern heat, a partially stagnant sea, and a plentiful supply of drainage from the town and from the ships at anchor in the bay. On the day of my visit there were 668 beds full out of a maximum of 750, medically superintended by Colonel Williamson and three other army officers, a quartermaster, and 10 civil surgeons. The new buildings erected during the war are of corrugated zinc and are of course quite clean and without any suspicion of insects. On this point I satisfied myself by examining many patients and some beds. The only criticism which I felt inclined to make was that 14 nursing sisters was an inadequate number for 668 patients, many of whom were in the enteric fever wards. The civilian visitor is also apt to wonder at the crowding of the beds in all hospitals, but it must be remembered that it is war-time and that the chief object is to get as many beds into a room or into a tent as possible while still allowing a little space by the side of each man's bed. The ordinary rules of floor space and cubic area are relaxed in war-time, and I must confess that in spite of overcrowding as judged by the eye I never went into any ward in which the nose detected the well-known human odour. The climate allows liberal roof ventilation and windows to be always open, and in army hospitals there are many convalescents who are only in the wards by night.

At Wynberg there are too important hospitals—No. 1 General Hospital, which has about 700 beds in the old barracks, and No. 13 General Hospital, which supplies 1000 beds in the zinc-and wood huts with which all South Africa is dotted about.

The sick officers are very comfortably housed in the Sanatorium at Claremont, one of the most beautiful suburbs of Cape Town. This is under the control of Major F J. Lambkin who has about 40 patients now, mostly convalescents. In deference to the wishes of the Cape Town authorities, the Imperial Yeomanry Hospitals Committee have now established a temporary tent hospital at Mackenzie's Farm, Maitland, where the Yeomanry depôt is situated. There are now 67 patients there including three officers, under the care of Mr. W. Turner, assistant surgeon to Westminster Hospital, to whom the temporary rank of Captain in the Royal Army Medical Corps has been given.

At Matjesfontein, which stands at a height of 3000 feet on the Karroo plateau, a Mr. Logan, who began life as a railway porter, has an estate of 116,000 acres and a hotel which has been used as a sanatorium for British officers until to-day when it is found too far away from the base of operations and is therefore no longer wanted.

Matjesfontein is a very good illustration of what can be done in the Karroo if water is provided. It is surrounded by uninviting plains of dry scrub and ant-heaps, without any other vestige of life. Mr. Logan told me that when he first settled there he used to have to bribe the engine-drivers with coffee to give him a little drinking water. Now the railway and the energy of one man have made the place a centre of production and trade and it boasts of wells, a church, a bank, and villa residences for those in search of invigorating air.

At Victoria Road, a few miles further along the railway, is a convalescent camp for 1000 soldiers, and there are now 540 there.

We next come to Deelfontein, 4600 feet above sea-level and nearly 500 miles from Cape Town, the spot pitched upon for the Imperial Yeomanry Hospital, which has established the reputation of being the best war hospital in South Africa. It consists of many huts, eked out by hospital marquees, and was originally intended for 520 patients. But the numbers have generally been above that. Once they rose above 1000, and they stand to-day at 640, though the numbers of sick in a military hospital depend rather upon whether the convalescents are retained or evacuated regularly. This hospital has now been open for nearly six months and has had the most complete staff of any hospital during this war, being composed of 19 medical officers, including an ophthalmic surgeon, a dentist, and an x-ray expert, 10 dressers, 40 nurses, 10 servants for sisters and St. John Ambulance orderlies, making a total of 200, besides native servants. Mr. A. D. Fripp and Mr. Raymond Johnson have now returned to London, and Dr. J. W. Washbourn is going to Pretoria to take Dr. F. M. Sandwith's place in the Yeomanry Hospital there. Some idea of the equipment at Deelfontein may be obtained when it is stated that about 3000 tons of stores were sent from London at a cost of over £20,000. Some very valuable x-ray work is being done there and it is almost the only war hospital where bacteriological investigation is being made. Much of the well-earned popularity of this establishment with all classes of patients is due to the cheeriness and tact of the commandant, Lieutenant-Colonel A. T. Sloggett, R.A.M.C.

Thirty miles beyond Deelfontein is De Aar Junction, once the great base of Lord Roberts's army, but now dwindled again to its normal dull proportions. Here there is to-day a stationary hospital containing only 150 men, all convalescents, and all insufficient to occupy the nursing sisters.

Norval's Pont is well known to all students of the war as the site of the bridge crossing Orange River and so separating Cape Colony from the Free State. The bridge, before it was blown up by the Boers in March, consisted of 13 spans of 130 feet each, and cost £76,000. Here the best hospital is the Edinburgh, with 200 beds in a series of huts, but the war is so distant that lately there were only five patients in it. Then there are a stationary hospital, and a rest camp, and a convalescent camp, and an officers' convalescent home which moved up from Kimberley at the end of June and consists of three marquees and several bell-tents. This can accommodate 20 officers and is due to the enterprise of Lady Maud Rolleston and Mrs. Seymour.

Orange River Colony.

At Springfontein there is an important section of No. 3 General Hospital, under the care of Colonel A. W. Duke, R.A.M.C. A convoy of 140 convalescents was brought to this hospital from Pretoria this week. Here the tents have wooden flooring and the marquees are placed side by side so as to increase the size of the ward and to facilitate nursing.

Bloemfontein, now recovered from its notorious epidemic of enteric fever, has only the large No. 9 General Hospital on the line about a mile from the town, for No. 10 General

Hospital, which was composed of various buildings in the town, is now being closed. Here was the Portland Hospital which did very good work until the authorities allowed it to close at the end of July, instead of accepting the desire of the staff to proceed to the front. It was a matter of surprise in Bloemfontein that the new *Leper Asylum*, which had never been inhabited by lepers, was not temporarily used as a hospital during the time of overcrowding, for it would have held at least 100. Probably its distance of two miles from the camp was the chief obstacle.

At Orange River there is a stationary hospital, and at Kroonstad, where Lieutenant-Colonel Wood is principal medical officer of all the hospitals and where lately almost every general of importance has been passing through, there is the excellent No 3 General Hospital containing 800 patients and officered by two majors of the Royal Army Medical Corps and 12 civil surgeons. This hospital is outside the town and close to the railway line for the obvious convenience of arrivals and departures.

The Grand Hotel was turned into a hospital of 35 beds for sick officers and was quite full from the middle of May till July, but it is now being closed as a matter of economy. This hotel is well supplied [illegible] de extremely comfortable, but [illegible] it required a large staff of nurses [illegible] is also here, must be praised. There are now 150 patients, mostly surgical, treated by a staff of civilian surgeons and dressers. The Dutch Reformed Church, helped out with tents, formed an additional hospital of 200 beds during the crowded time, but it was shut early in August. Churches are not ideal hospitals, because ventilation can only be obtained by breaking the top windows, and there is of course no provision of latrines. If the climate is perfect, the men do as well in the open air if there are no tents, but if there is any danger of storms of rain, dust, or wind, I cannot see why churches should not be utilised.

The Transvaal.

No one conversant with Johannesburg needs to be told that the civil hospital there is one of the best in South Africa. It stands in beautiful grounds outside the town and is now chiefly full of army patients. The lay nursing sisters were allowed to rejoin the religious sisters there at the end of July. No. 6 General Hospital was moved up here a month ago from Naauwpoort. Although this must obviously be the great business centre of the future Dominion of South Africa it is just now as melancholy as London on a Sunday. Shops and banks are hardly open, and those civilians who are not allowed to draw rations from the army have great difficulty in procuring the necessaries of life such as candles, matches, soap, paraffin, biscuits, milk, butter, flour, cheese, tinned food, &c

Pretoria is practically the headquarters of the army as well as being the political capital of the new colony and Surgeon-General Wilson early determined to prepare 2000 [illegible] 000 or 1500. The distribu- [illegible] out. In the plain east of the town near the railway running to and from the scene of the recent fighting towards Delagoa Bay are three hospitals side by side, all controlled by Lieutenant-Colonel A. H Keogh, R.A M.C These are No. 2 General Hospital (the best Royal Army Medical Corps hospital which I have seen in this war), the Langman Hospital of 150 beds which came up from Bloemfontein in August, and the Welsh Hospital which arrived about the same time from Springfontein. These three hospitals consist entirely of tents, except for various huts which contain stores and a brick destructor for burning the fæces of enteric fever patients after they have been mixed with sawdust and disinfectants. No. 2 General Hospital is one of the few army hospitals which possesses a disinfector for bedding. It is provided with such modern luxuries as a telephone and electric light for the central avenues of the camp. Near by is a most convenient convalescent camp to which patients are drafted from all the Pretoria hospitals until they can return to duty or until they are sent to the base. The Irish Hospital in the Palace of Justice has already been deservedly praised by all visitors. The building had never been occupied, it is one of the best in South Africa, and it has been adapted so easily into a splendid hospital that it is difficult to understand why the Royal Army Medical Corps declined to accept it when it was offered to them. Sir W. Thomson at once jumped at it when he arrived from Bloemfontein in July. He installed electric lighting, he erected latrines and kitchens behind the buildings, and he has created a hospital which it is hard to beat in any country if one remembers that the building was not constructed for a hospital. There are three buildings in the town, each holding less than 100 patients, in the State Model Schools, all belonging to the Royal Army Medical Corps. It will be remembered that it was in one of these schools that the British officers were imprisoned at the beginning of the war. One of the wards is still decorated by a skeleton and a war map, both so skilfully executed that the Boers varnished the wall to perpetuate them. It was from this prison that the officers contrived to get occasional news from some plucky girls at a school opposite. When Lord Roberts heard of this he sent to thank the young ladies and eventually had tea with them, to their huge delight.

The Burke Hospital for officers has now been closed. It was a Boer hospital originally during the war, and the English matron remained in charge of it all through the campaign. There are in addition a hospital at the Racecourse where the British prisoners were sent when sick, a hospital for natives, and a well kept leper asylum outside the town The most recent hospital of all in Pretoria bids fair to be the best.

On August 18th Lord and Lady Roberts opened the new Yeomanry Hospital on a site which they had themselves chosen as being the best in or near Pretoria. An estate of 130 acres belonging to a rebel English burgher who had enriched himself by plotting against England with the Transvaal Government, and who introduced among the Boers the soft-nosed bullets and other weapons of war, was commandeered for the purpose. His house, which is extremely well built and stands on a hill getting fresh breezes when Pretoria is airless and misty, accommodates 50 patients and has an operating theatre, while two neighbour- [illegible]

house. The credit of creating this hospital in the space of 12 days is due to Dr F M Sa[illegible] O. R. Kilkelly, the military comm[illegible] ceremony of opening the hospital [illegible] and a convoy of 99 sick and wounded arrived in ox-wagons at 10 30 P M from Commando Nek, two days distant. The medical staff of this hospital has been taken exclusively from young civilians who have recently held resident appointments at St Bartholomew's Hospital.

Cape Town, Sept. 6th.

THE MEDICAL SCHOOL DINNERS.

Charing cross Hospital Medical School.—The past and present students of the Charing cross Hospital Medical School held their annual dinner on Oct. 2nd at the Hotel Cecil. The gathering was an exceptionally large one, covers being laid for 230. The chair was occupied by Mr. John Harold who proposed the toast of "The Hospital and its Consulting Staff" and referred to the pleasure that all felt in listening to the third Huxley lecture delivered that afternoon by their honoured guest, Lord Lister. The next item in the programme was a song by Dr F. W. Mott who was uproariously compelled to give an *encore*. Mr. J. H. Morgan, in responding to the toast proposed by the chairman, referred in humorous terms to the fitful appearance of the numbers of the *Charing Cross Hospital Gazette* which, however, he regarded with the greatest attention, not unmixed with apprehension, for he had received severe criticism because he had made promises which had not been fulfilled. He now announced that the out-patient department for mental diseases was to be inaugurated at once under the care of Dr. Percy Smith. Next followed an excellent rendering of a song by Dr. Bathurst. Mr. Cantlie then proposed "The Past and Present Students" and referred to the fact that Huxley had been a free student at Charing-cross Hospital The origin of the free student was the outcome of the action of Mr. Hancock, who was asked to start the school. This surgeon was at Westminster Hospital and told the students there that if they would come to Charing-cross Hospital their medical education would be given them for nothing, with the result that students were not lacking at Charing-cross Hospital. He urged that to secure the blending of the old students with the new the medical school of Charing-cross Hospital should form an association and he would suggest that the first associate should be Lord Lister Mr. Charles Baly then sang "Queen of the Earth," and received a well-earned *encore*. The toast of "The Guest of the Evening" was proposed by Mr. H F. Waterhouse, who eloquently described the debt of gratitude which the medical world owed to the work of Lord Lister. This was responded to by Lord Lister in a charmingly modest speech; his reference to his memories of his old student days and the work of former times being uttered with evident emotion. The speech was worthy of the orator and his concluding compliment expressing his satisfaction at the abundant prosperity of the Charing-cross Medical School was received with loud applause "The Health of the Chairman" was given by Dr. Mitchell Bruce, and after a short reply from Mr. Harold the proceedings of the evening terminated. On Monday evening a conversazione was held in the school and the occasion was made attractive by musical and dramatic entertainments, exhibitions of chemical and electrical apparatus, x-rays, &c., the whole of the departments being thrown open to the visitors, of whom there was a great number. We congratulate the organisers of the conversazione upon its success. On the next occasion we hope the authorities will see that the various corridors are better lighted. In some places it was almost dark, the only source of light being a single naked gas flame. The electric light has been placed in the museum and the installation might be extended with advantage to the other departments of the school.

Westminster Hospital.—The annual dinner of the old students of Westminster Hospital and their friends, which was held at the Café Monico on Oct. 1st, under the chairmanship of Dr. W. H. Allchin, was, owing to the untiring energy of Mr. E. Canny Ryall, L.R.C.P. Lond., M.R.C.S. Eng., a decided success. Covers were laid for some 250 old students and guests, a fact which is significant because, as the chairman pointed out in proposing the toast of "The Westminster Hospital and Medical School," the number present was three times greater than on any previous similar occasion. Dr. Allchin alluded to the present position of Westminster Hospital as part of the newly-constituted University of London, remarking on the increased responsibilities of the school and its widened scope. The weekly Board of Governors was coöperating with the medical staff and during the past year a splendid pathological and clinical laboratory had been fitted up. As a significant and interesting fact he pointed out that in the very first list of the medical examination of London University in 1839 in a list of 20 individuals appears the name of a student of Westminster Hospital, and only three other schools in London were there represented. The Dean, Mr. A. H. Tubby, in responding, said that the progress of the school as shown by the number of entries was most satisfactory. Up to the present time the entries compared favourably with those of last year, which were double those of the previous year. Last year 80 per cent. of the students passed. The toast of "The Old Students," coupled with the names of Mr. W. Gandy and Dr. J. Swain, was proposed by Dr. T. Colcott Fox. "The Present Students" was proposed by Dr. F. de Havilland Hall and responded to by Mr. G. V H. Fairhall and Mr. A. R. Roche, the editor of the "Westminster Hospital Gazetteer," otherwise known as "The Broad Way." Among the other toasts were "The Visitors" and "The Chairman," the speakers being Mr. W. G. Spencer, F.R.C.S. Eng., the Rev. J Garton, Professor Sims Woodhead, and Mr. T. Bond, F.R C.S. Eng. An excellent musical programme added much to the pleasures of a delightful evening.

King's College Hospital.—The annual dinner of the old students of King's College Hospital was held at the Hotel Cecil on Oct 1st. The Hon. Sir John Cockburn, M.D., K.C.M.G., presided, and the number of those present was larger than in any previous gathering of old King's College students. The usual toasts including "King's College" and "King's College Hospital," were drunk and a message from the chairman of the University College Hospital dinner in the same hotel was warmly appreciated and duly reciprocated.—The Principal of King's College replied for the College and hospital and Mr. William Rose most felicitously proposed the health of his old fellow-student and gold medalist who had deserted medicine and become the Agent-General for South Australia. Professor Watson Cheyne and Mr. G. Lenthal Cheatle were warmly greeted on their return from South Africa. The death of Surgeon Captain M. P. Hughes was referred to most feelingly.

St Thomas's Hospital.—The annual old students' dinner was held on Oct. 2nd in the Whitehall Rooms of the Hôtel Métropole. There were 146 old students and guests present and the chair was taken by Dr. O. T. Aveling. After the toast of "The Queen" Sir William Mac Cormac proposed the toast of "St. Thomas's Hospital and Medical School, Past and Present." He alluded to the cordial relations existing between the staff and governors and paid a tribute to the work done by the St. Thomas's contingent at the Cape, which numbered some 50 men. The toast was coupled, firstly, with the name of the treasurer, Mr. J. G. Wainwright, who gave a brief outline of the financial condition of the hospital, and enumerated, amongst other improvements, the rebuilding of the operating theatres, the ophthalmic and casualty departments, and asserted the determination of the governors to spare no expense in keeping the equipment of the hospital at least second to none. The Dean, Dr. H. G. Turney, in an amusing speech, reviewed the chief changes of the year and alluded in sympathetic terms to the death of Rupert Fawssett while on active service in South Africa and to the retirement of Dr. Payne on to the consulting staff. Dr. F. G. Nicholson having also responded on behalf of the old students the health of the chairman was proposed by Dr. Payne who referred to Dr. Aveling's qualities as a practitioner, to his brilliant hospital career, and to his success in the field of sport. Dr. Aveling, in reply, thanked the company for the way in which they had received the toast and said he believed he was the first man to score a goal in the interhospital football matches. The usual vote of thanks to the secretaries was proposed by Dr. Solly and suitably acknowledged. Mr. G. H. Makins, in answer to repeated calls for a speech, described the conditions under which he had met old hospital men at the seat of the war and pointed out that St. Thomas's students were to be found acting as civil surgeons at the base hospitals and up to the firing line.

Middlesex Hospital.—The annual dinner of present and past students of the Middlesex Hospital took place at the Trocadéro Restaurant on Oct. 1st. Mr. William Lang, ophthalmic surgeon to the hospital, occupied the chair and about 130 persons took part in the proceedings. The Royal toasts were proposed by the Chairman. Sir Richard Douglas Powell proposed "The Services." In the course of his speech he referred to the medical departments of the navy and army and read a list of the names of Middlesex Hospital men serving with the forces in South Africa. He also read portions of a most interesting letter which he had received from an officer of the Royal Army Medical Corps serving in South Africa. The writer remarked that "a more cruelly undeserved attack it would have been difficult to conceive" than that which had recently been made upon the work of that department, and he referred in detail to the difficulties which were encountered on the march to Bloemfontein. Sir Richard Douglas Powell believed that the investigation now being conducted would terminate in a triumphant vindication of the Royal Army Medical Corps. The toast was responded to by Dr. Edward Stewart, who had recently returned from service in South Africa and had been in charge of a hospital train. He considered the work rendered by the Royal Army Medical Corps to have been magnificent. The toast of "The Middlesex Hospital and Medical School" was proposed by the Chairman, who referred to the extensive alterations which had been made in the buildings of the medical school, the laboratories and lecture-rooms being admirably fitted with all modern appliances for study and research work. He also drew attention to the opening of the new cancer wing and to the research work which was there being carried on. The toast was responded to by Colonel T. Lambert Mears and Mr. Pearce Gould (in the place of the Dean, Dr. W. Pasteur, who was unavoidably absent). The toast of "Past and Present Students" was proposed by Mr. Henry Morris and replied to by Mr. E. A. Fardon and Mr. F. D Blandy, the Senior Broderip Scholar. The toast of "The Visitors" was proposed by Dr. J. Kingston Fowler and replied to by Professor Clifford Allbutt, who had delivered the annual address in the afternoon, and Mr. Wilhelm Ganz, as for many years past, kindly supplied the musical programme of the evening. "The Health of the Chairman" was proposed by Dr. Sidney Coupland, acting for Dr. W. Cayley. Señor Guetary, Mr.

James A. Bovett, and Mr. Paul Stoeving added to the success of the evening by a selection of songs and violin solos.

THE PLAGUE IN GLASGOW.

THERE is but little fresh news to be chronicled concerning the outbreak of plague in Glasgow. Since our last issue two patients have died in the Belvidere Hospital from the disease—namely, a man whose death was notified on Oct. 2nd, and an infant, aged two weeks, born in the hospital of a mother who herse [illegible] The latest advices from Glasgow sh [illegible] of cases in the hospital is 21; of [illegible]

DISTRIBUTION OF PRIZES AT ST. THOMAS'S HOSPITAL.

THE occasion of the distribution of prizes and certificates to the successful students of St. Thomas's Hospital Medical School on Oct. 2nd was taken advantage of by the many friends of the school and hospital to attend in great numbers. The usual address was given by Sir William MacCormac, the President of the Royal College of Surgeons of England. The treasurer of the hospital, Mr. J. G. Wainwright, presided over the meeting and in a few well-chosen words welcomed back Sir William MacCormac from the scene of war. After the prizes and certificates had been duly given away by Sir William MacCormac he proceeded to deliver his address, and pointed out for the consolation of the unsuccessful students that the real value of trying for a prize was in the effort to succeed. The prize-winning spirit was not altogether an unmixed good because it might be carried too far, and it had this drawback, that it tended rather to specialise the student's work. Examinations were carried to a further degree in China than anywhere else; everyone was examined till he was quite an old man, and it was the only entrance into public life. He thought that men might have perhaps too many examinations. Students were harassed by continual examinations, and examiners in chemistry, physiology, and anatomy were often experts who regarded their particular branch as of the first importance. The most lasting and valuable information a student acquired was that which he taught himself. There was too much spoon-feeding done in the medical schools. Though he (Sir William MacCormac) had not made the best use of his first year of study as a student he would urge that the work in that period should not be neglected. In the fine old times the practitioners of England belonged to the "College" and the "Hall," which were good enough for them and for their patients. But by degrees an opinion had sprung up that those who attached M.D. to their names were very superior persons. It was but an example of the superstitions that cling to medicine that there should be a cabalistic value in the possession of these letters. But superstition or not the want was felt and that want would now be supplied. It was certain that at the present time young professional men were hard to find, the State found the supply insufficient and the competitive examinations were often not competitive, *the number of candidates being less than the vacancies.* The great steamship companies that used to have a waiting list had now difficulty in obtaining men to fill their surgeons' posts. The state of overcrowding in the profession which was prevalent a few years ago no longer existed to anything like the same extent. In 1851 there was a medical man for every 1393 inhabitants, in 1880 there was one for every 1754, and in 1898, in spite of the increased population, it was one for every 1150. It would seem from evidence which they possessed that the annual increase in the number of medical men was not keeping pace with the increase of population in the United Kingdom. The average annual increase of medical men during the past three years had been 450; the average during the five previous years was 845 or nearly double that number. The late Sir James Paget investigated the careers of a thousand medical students and in 16 years he found that 23 were distinguished men, 66 had arrived at a considerable amount of success, 507 were doing well, 128 had died, and 276 had either left the medical profession or were put down as failures. In the opinion of the speaker the present time was most favourable for entering the profession with the assurance of earning a competency.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6079 births and 4110 deaths were registered during the week ending Sept. 29th. The annual rate of mortality in these towns, which had been 19·6, 18·2, and 18·1 per 1000 in the three preceding weeks, rose again last week to 18·5. In London the death-rate was 16·7 per 1000, while it averaged 19·6 in the 32 provincial towns. The lowest death-rates in these towns were 11·1 in Bradford, 11·9 in Halifax, and 14·7 in Croydon, in Portsmouth, and in West Ham; the highest rates were 23·0 in Liverpool, 23·6 in Blackburn, 26·6 in Manchester, and 27·6 in Salford and in Sunderland. The 4110 deaths in these towns included 776 which were referred to the principal zymotic diseases, against numbers decreasing from 1422 to 771 in the four preceding weeks; of these 495 resulted from diarrhœa, 79 from diphtheria, 76 from "fever" (principally enteric), 70 from whooping-cough, 30 from measles, and 26 from scarlet fever. The lowest death-rates from these diseases were recorded in Birkenhead, Halifax, Bradford, and Newcastle; and the highest rates in Wolverhampton, Norwich, Leicester, Preston, and Sunderland. The greatest proportional mortality from scarlet fever occurred in Sunderland; from whooping-cough in Croydon, Swansea, Oldham, Preston, and Sheffield; from "fever" in Portsmouth, Plymouth, and Preston; and from diarrhœa in Wolverhampton, Manchester, Burnley, and Sunderland. The mortality from measles showed no marked excess in any of the 33 towns. The 79 deaths from diphtheria included 40 in London, nine in Leicester, and four in Sheffield. No fatal case of small-pox was registered last week in any of the 33 large towns; and only two cases of small-pox were under treatment in the Metropolitan Asylums Hospitals on Saturday last, Sept. 29th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1938, against numbers increasing from 1702 to 1804 on the four preceding Saturdays; 318 new cases were admitted during the week, against 213, 243, and 269 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 124, 161, and 203 in the three preceding weeks, declined again last week to 187, and were seven below the corrected average. The causes of 40, or 1·0 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Birmingham, Leicester, Bradford, and in 14 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Leeds, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·5, 18·9, and 18·9 per 1000 in the three preceding weeks, was again 18·9 during the week ending Sept. 29th, and was 0·4 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 17·1 in Dundee and 17·2 in Leith to 20·2 in Perth and 25·1 in Aberdeen. The 584 deaths in these towns included 49 which were referred to diarrhœa, 12 to whooping-cough, 12 to "fever" (including three deaths from bubonic plague), seven to diphtheria, six to scarlet fever, and five to measles. In all 91 deaths resulted from these principal zymotic diseases, against 83, 98, and 112 in the three preceding weeks. These 91 deaths were equal to an annual rate of 2·9 per 1000, which was 0·6 below the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had been 42, 54, and 62 in the three preceding weeks, declined again last week to 49, of which 21 occurred in Glasgow, 14 in Edinburgh, four in Aberdeen, and four in Leith. The deaths referred to different forms of "fever," which had been seven in each of the two preceding weeks, increased to 12 last week, and included seven (three of which were fatal cases of bubonic plague), in Glasgow. The deaths from whooping-cough, which had declined from 25 to 20 in the four preceding weeks, further fell last week to 12, of which five were registered in Glasgow, three in Dundee, and two in Greenock. The fatal cases of diphtheria, which had increased from three to 11 in the four preceding weeks, declined again to seven last week, and included four in Glasgow. The deaths from scarlet fever, which had been seven and four in the two preceding weeks, rose again last week to six, and were all recorded in Glasgow, where three of the five deaths from measles were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 70 and 101 in the two preceding weeks, declined last week to 100, but showed an excess of 33 over the number in the corresponding period of last year. The causes of 31, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·2 and 24 5 per 1000 in the two preceding weeks, was again 24·5 during the week ending Sept. 29th. During the 13 weeks of the quarter ending on Saturday last the death-rate in the city averaged 22·7 per 1000, the rate during the same period being 17 9 in London and 16 9 in Edinburgh. The 164 deaths belonging to Dublin registered during the week under notice corresponded with the number in the preceding week, and included 25 which were referred to the principal zymotic diseases, against 44 and 31 in the two preceding weeks; of these 18 resulted from diarrhœa, four from "fever," and three from whooping-cough. These 25 deaths were equal to an annual rate of 3·7 per 1000, the zymotic death-rate during the same period being 2·5 in London and 2·9 in Edinburgh. The fatal cases of diarrhœa, which had been 20, 27, and 24 in the three preceding weeks, further declined last week to 18. The deaths referred to different forms of "fever," which had been seven and three in the two preceding weeks, rose again to four last week. The three fatal cases of whooping-cough were equal to the number recorded in the preceding week. The 164 deaths in Dublin last week included 49 of infants under one year of age and 33 of persons aged upwards of 60 years; the deaths of infants exceeded the number in the preceding week, while those of elderly persons showed a slight decline. Four inquest cases and three deaths from violence were registered, and 53, or nearly one-third, of the deaths occurred in public institutions. The causes of 13, or nearly 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon G. Kirker to the *Trafalgar*. Staff Surgeons: P. E. Maitland to the *Sybille* and A. Cropley to the *St. George*. Surgeons: E. H. McSherry to the *Pallas*; and T. T. Jeans to the *Thunderer* for Pembroke Dockyard.

ROYAL ARMY MEDICAL CORPS.

Major J. Hickman has joined at Woolwich.

ARMY MEDICAL RESERVE OF OFFICERS.

To be Surgeon-Majors: Surgeon-Captain George Hollies; Surgeon-Captain George Henry Darwin, 2nd Volunteer Battalion Manchester Regiment.

VOLUNTEER INFANTRY BRIGADE.

Northern Counties: Surgeon-Major G. W. Brumwell, 2nd Volunteer Battalion the Border Regiment, to be Brigade-Surgeon-Lieutenant-Colonel, on appointment as Senior Medical Officer to the Brigade.

TRANSVAAL WAR NOTES.

Lieutenant-Colonel J. J. Falvey, R.A.M.C., Captain Vidler, R.A.M.C., Lieutenant M'Loughlin, R.A.M.C., and Captain O'Connor, M.M.S.O., are on passage home from the Cape in the *Kildonan Castle*. Major Sir J. R. A. Clark, R.A.M.C., and Major Moir, R.A.M.C., are on passage home from the Cape in the *Briton*.

The following officers of the Royal Army Medical Corps have been discharged from hospital and have returned to duty:—Lieutenant A. H. H. Niblett, Lieutenant J. Tandy and Lieutenant Colonel Battersby.

The *Avoca* arrived at Southampton on Oct. 2nd with 18 officers and 259 men invalided and wounded from South Africa.

THE APPOINTMENT OF COMMANDER-IN-CHIEF.

The retirement of Lord Wolseley from the office of Commander-in Chief of the British Army and the appointment of Lord Roberts as his successor are events which should not be allowed to take place without a word of comment on our part. It goes without saying that Lord Wolseley is a thorough soldier. He has had a most distinguished career and his brilliant military services will always, and very deservedly so, occupy a prominent place in the military history of this country. His conduct of the Egyptian campaign of 1882 was marked by great originality of conception and boldness of execution. His lordship, it will be remembered, did not give that amount of credit and support to the medical service on that occasion which the officers of that service thought that they had a right to expect; but that is no reason why his ability and great services in the field and to the nation should not be cordially recognised. There is no need to touch upon Lord Roberts's services because they are well known and speak for themselves. The officers of the medical service have every reason to be satisfied with, and grateful to him for, his handsome recognition of their work in the present war.

THE ASHANTI RISING.

But for the fact that the public mind has been so occupied with events which have been taking place in South Africa and China, the military operations against the Ashantis would no doubt have received far more attention than has been bestowed upon them. The fighting has been severe; the operations have apparently been skilfully planned and conducted, and several of the engagements with the enemy have been of a brilliant kind. Owing to the climate and to the nature of the country and to the fact that the troops have frequently had to advance through dense bush, the campaign has been a very trying one and the progress has been slow. The force on the British side has been mainly a native one, composed of such corps as the Central African Rifles, West African Frontier Force, and others, and it is probably owing to this fact that it has been relatively healthy and that the men have suffered much less from climatic disease than might have been expected. We regret to notice that the death of Dr. Langstaff, serving with the force, has been reported in a letter from the special correspondent of the *Standard*.

THE LATE LIEUTENANT-COLONEL M. R. RYAN, R.A.M.C.

At a recent meeting of the sanitary board at Hong-Kong, Mr. J. Bell, L.R.C.P. Lond., M.R.C.S. Eng., vice-president and acting principal medical officer, the chairman, brought forward a resolution of regret for the loss which they had sustained by the death of one of their members, Lieutenant-Colonel M. R. Ryan, R.A.M.C., who had succumbed to an attack of pneumonia. He was a prominent member of the board, which could ill afford to lose a member, especially when that member was a medical man, and one who had served in one of the best medical schools in the world. He begged to move that the board express its deep regret at the death of Lieutenant-Colonel M. R. Ryan, R.A.M.C. The resolution was declared carried.

"Audi alteram partem."

"THE NOTIFICATION OF PLAGUE."

To the Editors of THE LANCET.

SIRS,—In an annotation in THE LANCET of Sept. 29th, p. 959, on the notification of plague you truly say that it is undoubtedly difficult for a practitioner to diagnose a disease which he has never seen. I would add that the difficulty becomes extreme when you have—as is often the case with poor people who can only afford to pay for one visit—to make your diagnosis on a first, or even a second, examination in a dark room with filthy surroundings. You also wisely advise your readers to go carefully over the Glasgow cases which you have fully published from week to week. It is evident that the early diagnosis in general practice of plague is of national importance, and as we all learn far more from a mistaken than from a correct diagnosis I venture to supplement the report of one of the cases mentioned in Dr. A. K. Chalmers's valuable weekly report and at the same time to bring out two interesting facts from a practitioner's point of view. He refers to this case in this week's report as "Rosina M., unmarried, aged 25, of 23, Florence-street, sickened on August 23rd, and her illness was not recognised till Sept. 10th. She had no regular medical attendance."

I was called in to see this patient for the first time on Sept 10th, and having seen the first cases, the Malloy cases, as well as the other cases at present in Belvidere Hospital, I had no difficulty in diagnosing bubonic plague, for in answer to my question: What is the matter with you? she at once directed my attention to very palpable, painful buboes in each groin. Moreover, she worked beside the other young women who had been to the "wake" in Rose-street and are now in Belvidere Hospital with plague I learned from her mother that during her illness of 18 days she had been seen twice by a medical man. His first visit was when she sickened and was "raving," and his second visit was 14 days later. On calling on him he informed me that on his first visit her temperature was 104° F., but on his second visit it was normal He thought, not unreasonably, that the buboes were most probably gonorrhœal I may add that when I saw her on Sept 10th her temperature was normal, there was no rash or mottling of the skin, nor was there anything apparently the matter with her but the painful buboes in each groin. Now the two points I wish to emphasise are (1) that unless seen early the temperature, which would be a valuable differentiation sign between plague buboes and gonorrhœal buboes, would be *absent; and (2) that in my limited experience in* cases where I suspected gonorrhœa in women I have never seen buboes although I often see them in men. I think that the common sequel of gonorrhœa in women is not a bubo but inflammation and suppuration of the vulvo vaginal or Bartholin's glands. If buboes are a rare sequela of gonorrhœa in women—and an authoritative statement at present on this point might be important—the fact of finding buboes in a woman, even with a history of suspected gonorrhœa, and especially with a rise of temperature, ought at the present time strongly to suggest bubonic plague.

I am, Sirs, yours faithfully,

Glasgow, Sept. 29th, 1900. THOMAS COLVIN.

"INOCULATION AGAINST TYPHOID FEVER."

To the Editors of THE LANCET.

SIRS,—On seeing the leading article on this subject in THE LANCET of Sept. 29th (p 952), I again studied the official report referred to, but must confess that I can see no reason to modify my criticism of it in the *Times* of Sept 24th Paragraph 3 of the report seems quite explicit, and the inoculation was certainly put a stop to at one time. Here is the passage:—

> "..... and it appears to have been understood from the concluding portion of the War Office letter of 24th January, 1893 that the [illegible]
>
> [illegible] on the facts becoming known, however, *orders were issued to stop further inoculations, and the treatment has accordingly been abandoned*

The italics are mine. We have a perfectly clear statement, not only that the "inoculation at the public expense" was prohibited, but that when it became known that Professor Wright, then in India on the Plague Commission, was carrying on "voluntary operations at private cost," these, too, were put a stop to. If this is not "express prohibition" of inoculation against typhoid I do not know what is—at all events it seems to have effectually stopped it for a considerable period. That inoculation was resumed after August, 1899, has nothing to do with the question raised by me. I ask *why it was* that the measure was checked in 1898 I submit that though Government might reasonably have refused to encourage "inoculation at the public expense"—though even this was in my own humble opinion thoroughly bad policy—yet they had no justification for going so far as to stop Dr. Wright's private [illegible] doing so they practically took [illegible] inoculation is *harmful*—that their [illegible] was going about poisoning their [illegible] think so, why did they prohibit the measure?

I am, Sirs, yours faithfully,

Liverpool, Oct. 2nd, 1900. RONALD ROSS, D.P.H.

BERI-BERI.

To the Editors of THE LANCET.

SIRS—Into the Provincial Hospital, Port Elizabeth, to which I was attached for many years, cases have been admitted from ships arrived from the East the diagnosis of which has been disputed They have presented symptoms I think common to two diseases—"malaria," so called, and "beri beri" Being health officer to the port as well as medical officer to the hospital some eight or 10 years ago I sent on shore several members of a crew who had been in an Eastern port. They were stated to have suffered from "fever" more or less for a considerable time; they presented, if I remember rightly, [illegible] fever-stricken patients—anæmia, [illegible] and more or less œdema of the [illegible] miliar to anyone who has lived in the East, Mauritius, or Madagascar. It so happened, I think, that the subject of beri-beri was being written and talked about at that time and it became a disputed point whether the men should be allowed to remain in or be removed to the lazaretto Having on previous occasions admitted men in like condition without ill result following I pressed their being allowed to stay, which was done. No harm came from it, and after good nursing and rest they were allowed to go out to be sent home by steamer on a certificate from me that no harm was to be anticipated. No deaths occurred Had these been the subject of beri-beri the outcome of the affair, I imagine, would have been very different as regards the patients themselves. I had never seen a case of beri-beri, neither had any of the local medical men All we knew of the malady was from books. Since then I learn that "beri beri is an endemic form of 'peripheral neuritis,' pathologically in the same category as diphtheria, alcoholic, and other forms of neuritis."[1] In a late Port Elizabeth paper I learn that cases have occurred in Algoa Bay of a like nature, that the port officer advised their admission into the Provincial Hospital, that the hospital authorities objected, and I believe the men were sent to a lazaretto.

To prevent any further friction in similar cases I should like to be informed in the pages of THE LANCET what is the differential diagnosis between cases of long-standing malaria and the disease called "beri-beri" Some of your readers who have had experience in the East might supply this information with great service to patients and hospital authorities. If there be a well-recognised "bacillus beri-beri," by sending a specimen of blood or local effusion to the nearest bacteriological institute—e g, that of Graham's Town—this question might be decided at once and acted on. And what is the difference between the bacillus of "malaria" fever and that of beri-beri, if there be any? Is beri beri considered infectious? *It appears to be frequently fatal, hence* the necessity of strict care in admitting such cases; but how to prove their nature? From experience I know nothing of beri-beri, but from books only The difference between extreme cases of malaria and beri-beri is difficult to decide and I apprehend that the bacteriological examination of blood and tissues of these cases is the only scientific guide for action. The evidence of experiment and experience is much desired.

I am, Sirs, yours faithfully,

Oct. 2nd, 1900 F. ENSOR, M.R.C.S.

"ANNUAL REPORT FOR 1899 ON BIRTHS, DEATHS, AND MARRIAGES IN IRELAND."

To the Editors of THE LANCET.

SIRS,—In thanking you very heartily for the complimentary remarks you were pleased to make in your review in THE LANCET of Sept 29th, 1900 (p 963), of the Annual Report of the Registrar General for Ireland for 1899 on my meteorological observations I wish to correct a slight error into which you have fallen. You speak of observations taken by me at my country residence in county Wicklow. I have no country residence, and for the observations in question I am indebted to my friends, Mr. R. Cathcart Dobbs, C.E., J.P., of Knockdolian, Greystones, county Wicklow, and Dr. B. H. Steede, the able resident medical superintendent of the National Hospital for Consumption for Ireland, which is situated near Newcastle, county Wicklow. This is now a fully equipped second order meteorological station at which observations of great value are being systematically taken.

---

[1] Brit. Med. Jour, Oct. 13th, [illegible]

I am, Sirs, yours faithfully,
JOHN W. MOORE, M.D. Dub., F.R.C.P. Irel.
Dublin, Oct. 1st, 1900.

THE SMOKE NUISANCE.

To the Editors of THE LANCET.

SIRS,—The Coal Smoke Abatement Society is in no sense moribund. The funds at present at its disposal only admit of the employment of two inspectors, who are constantly at work, and whose reports are submitted to the committee every fortnight. These show that the state of London as regards the smoke nuisance is improving but little, and this is due entirely to the negligence of vestries (and more than negligence) in enforcing the Act and the apathy of the London County Council and Parish councils. This negligence and apathy are due to various causes; prominently in the vestries and parish councils the offenders are members or friends of members. Until the law is changed and the responsibility of prosecution is withdrawn from the vestries and reinstated in the hands of the police there is little chance of a real diminution of the evil. Jobbery is rife and bribery is constant. Reports which our inspectors have laid before the County Council, parish councils, and the vestries have been ignored or given the lie to by inspectors employed by those bodies. Members of my committee, myself included, have verified our inspectors' reports, and we know them to be true. We equally know that representations furnished by their inspectors to the County Council, parish councils, and vestries have been false. A meeting of my committee will be held at 14, Buckingham-gate, on Thursday, Oct. 11th, at 5 P.M. I am going to try to call a public meeting at St. James's Hall as soon as the elections are over, when I feel sure that you will give us your valuable aid from the point of view of health.

I am, Sirs, your obedient servant,
Hammersmith, Oct. 2nd, 1900. W. B. RICHMOND.

To the Editors of THE LANCET.

SIRS,—Every inhabitant of London will be thankful to you for drawing attention to the smoke nuisance. At the present moment I am engaged with a great number of other inhabitants in South London in combating the nuisance caused by the smoke from the chimney of the South London Electric Light Corporation. The said chimney emits volumes of black smoke which partly emanates from burning refuse from the streets of the parish of Lambeth. The Electric Light Corporation has on several occasions been fined for the smoke nuisance, but they simply pay the small fine inflicted each time somebody takes the trouble to institute proceedings and the nuisance goes on as before.

The inhabitants of Lambeth, as well as those of Camberwell, have issued memorials to compel the Lambeth parish to take action, but we fear that the fact of the vestry having a contract with the South London Electric Light Corporation for the burning of their street refuse will make them very reluctant to take such action as they are otherwise compelled by Act of Parliament to institute. The smoke contains gases coming from the consumed refuse which are of the most objectionable description and, in my opinion, are necessarily injurious to health. We are very thankful for the assistance we receive from journals of such importance as yours, as only condemnation by public opinion may succeed in compelling the vestry authorities to do their duty.

I remain, Sirs, yours faithfully,
Oct. 2nd, 1900. L. R.

VACCINATION PROSECUTION.—At the Gloucester City police-court on Sept. 28th, six persons were summoned for neglecting to have their children vaccinated. All the cases were eventually dismissed as the vaccination officer was unable to prove service of the notices to vaccinate.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Rebuilding of the Manchester Royal Infirmary.

A REVOLT against the ascendancy of the pavilion plan of hospital building has taken place. Some time ago a special committee was appointed by the trustees of the Manchester Royal Infirmary which has had the proposal to build a new infirmary under consideration, and a special committee of 11 members—seven elected by the board of management and four by the medical board—was then appointed "to deal with the question of ascertaining whether or not a hospital suitable in every way could be built on a plan other than the pavilion system." The medical board expressed the opinion that it was uncertain whether the pavilion system was as absolutely perfect as it had been thought to be and that it might be well to consider whether some other system which required less ground could not be adopted. Opinions on the subject were requested from Lord Lister, Sir William Mac Cormac, Sir Thomas Smith, Sir Samuel Wilks, Professor Macewen, Professor Thomas Annandale, Dr. T. Clifford Allbutt, Dr. J. F. Goodhart, Mr. Frederick Treves, Mr. Howard Marsh, and Mr. Timothy Holmes. Of these, Lord Lister, Sir Thomas Smith, Professor Macewen, and Sir William Mac Cormac thought that the pavilion plan was ideally the best, but that it was quite possible to build a satisfactory infirmary "on other than the pavilion system." Mr. Holmes was opposed to the pavilion plan, and Mr. Marsh considered that it was not only not essential but that it was in some respects inconvenient and open to positive objection. Dr. Clifford Allbutt and Professor Annandale thought that the pavilion form was the best. Dr. Goodhart, Mr. Treves, and Sir Samuel Wilks expressed no opinions. The report of this committee was considered by the board of management on Sept. 24th, and after discussion it was accepted unanimously. Mr. J. Hardie, the chairman of the medical board, wrote: "Our report is really a most important one. I know of none to equal its importance. Not only has no consensus of professional opinion been before obtained, but no such inquiry as we have made has ever been carried out. Hitherto it has been thought that medical opinion was wholly in favour of the pavilion plan exclusively. We have found that that is a complete mistake. The consequence of this is that in future hospital authorities will be less fettered and will give effect to their wishes at lessened cost." It was resolved that the special committee should be instructed to carry out the second part of the resolution adopted by the board of management on Feb. 9th which gives authority to take steps to obtain suitable plans and estimates and to incur any necessary expense in connexion therewith. Everything, therefore, seems to promise plain sailing for the scheme of rebuilding on the present site. But the present site is not the best for the infirmary in every respect, though it is the best for a much-wished-for scheme that might be carried out if the corporation could only purchase the whole of the ground. A noble art gallery and free library could be built on the site if the corporation could afford to buy it, and a hospital might be built elsewhere on a site more suitable to the present condition of the town, and according to plans embodying modern knowledge and wisdom so far as attainable. But the corporation has great schemes on hand that draw heavily on its resources, so the question is whether it can afford to buy the ground. On the other hand, no encroachment on the open space round the infirmary will be allowed and it is very doubtful if the increase of hospital accommodation urgently required can be obtained without extending the present area of the building. So that it seems as if, to quote a leading article in one of the local papers, "the new century will open with matters in about the same position as they were seven years ago."

Various Sewage Difficulties.

In THE LANCET of August 11th, 1900 (p. 464), the condition of the "Black Brook," which diffuses its noxious odours most liberally as it flows through Birch Park, one of the open spaces of Manchester, was mentioned in terms perhaps scarcely strong enough to express truly its pre-eminence as a nuisance. It is satisfactory, therefore, to know that the Reddish Urban District Council have been fined £20 for one case of pollution and £5 for a second, with £5 costs. The Mersey and Irwell Joint Committee made an order as to the purification of the stream so long ago as 1894, but with as little result as if the council had been composed of Chinese mandarins. The council now, however, promise immediate attention to the sewage works and in the meantime they will take temporary steps for the abatement of the nuisance It is intimated that the Gorton Urban District Council are likewise about to be summoned for fouling the brook. At the meeting of the Prestwich Urban District Council on Sept. 12th it was said that they were doing everything possible for dealing with the sewage. But as to a scheme for the Rainsough part of the district they had a grievance against the Local Government Board, and the facts seem really to justify the heading of a paragraph in a local journal—"The Strange Ways of the L G B" The Board suggested certain alterations in the scheme of the council which would add £162 to the cost. To save time the alterations were accepted and an application was made for leave to borrow the extra money, but no reply was received and the work was therefore delayed. The council did not seem to think that that was fair treatment and they considered that if the Board brought district councils into existence it ought to help them to carry out their work. As a member said: "People talked about the state of the War Office, but that was nothing in comparison with the state of the Local Government Board." On this point there is a remarkable unanimity among district councils. The Withington Urban District Council and the Stretford Urban District Council are suffering from somewhat strained relations, for the sewage farm of the former offends the senses of the clients of the latter, and the Local Government Board have written a letter on the subject, to which the clerk and surveyor of the Withington Council have "been instructed to prepare a suitable reply." They are also informed by the Mersey and Irwell Joint Committee that their "effluent after land treatment was very unsatisfactory on July 2nd and 10th." The clerk was instructed "to explain the position of the council," which position the committee no doubt know quite well, "and to state that they were doing all in their power to improve matters" These are wholesome signs of activity, and real work is being done to lessen the pollution of the streams. The consequences of ignorance and neglect in times gone by may press somewhat heavily nowadays, but the noxious and disgusting condition of most of our streams is such a disgrace to the civilisation of the day that the crusade against it must be carried out to a successful termination Since the above was written the Gorton District Council have been fined a nominal sum on promise of constructing additional works within six months to deal with the increased quantity of sewage. Five years ago sewage works were constructed, but since then the population has increased from 16 000 to nearly 30,000, and they are now inadequate. At the meeting of the Heaton Norris District Council on Sept 20th the pollution of this now notorious brook—in this part of its course called Gore Brook—was mentioned as greatly affecting Heaton Norris, and satisfaction was expressed "that so firm a stand had been taken by the Mersey and Irwell Joint Committee."

Oct. 2nd

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Threatened Outbreak of Bubonic Plague.

No case of bubonic plague has occurred in Dublin Some alarm was, however, caused recently by the report that a sailor on board a vessel which had just arrived from Glasgow was suffering from illness. Dr J. M. Day of Cork-street Fever Hospital, who had taken the precaution to make himself familiar with the symptoms of bubonic plague in Glasgow, made an examination of the man and pronounced that the disease was not plague. It seems very fortunate that no cases have occurred in Dublin, for the difficulty about isolation still exists Mr. Ryan, the public health officer of the Glasnevin district, reported to the rural district council on Sept 26th that Beneavin, the house proposed to be used for the reception of plague patients, was unsuitable because it was situated by the side of the public road and within a very short distance of the town and of the congested district of Finglas. The sanitary arrangements were, moreover, stated to be defective and objectionable. It was decided to send a copy of the report to Sir Charles Cameron

The New Veterinary College in Dublin.

A deputation from the new Veterinary College waited on the Pembroke Urban Council on Oct 1st in reference to some opposition to the site of the new buildings. The deputation comprised Sir Christopher Nixon, Sir Thornley Stoker, Professor George Fitzgerald, F.T.C.D, Sir Charles Cameron, C B., Mr. James Talbot Power, D L, and Professor Mettam, principal of the college. Sir C. Nixon urged the council not to oppose the institution and he expressed the regret of the governors of the college that their architect had failed to submit their temporary plans to the council. The authorities were pledged to open the college to students on Oct. 3rd and some alterations in the present buildings were necessary until the permanent offices of the college should be ready. The permanent buildings, he went on to state, would cost about £25 000 and would be of the most up-to-date type. He believed that this college was of the greatest importance to the national and scientific interests of the country, and he hoped that the council would not throw any difficulties in the way of its establishment. After the withdrawal of the deputation the council passed a motion that the plans of the permanent buildings of the college should be sent to the surveyor of the council for a report by him to the Public Health Committee.

Meath Hospital and County Dublin Infirmary.

The vacancy on the surgical staff of the Meath Hospital caused by the lamented death of Sir William Stokes was filled on Sept. 27th by the election of Mr. Richard Lane Joynt, M.D. Dub., F R.C S. Irel.

St. Vincent's Hospital, Dublin.

The introductory address in St. Vincent's Hospital for the present medical session was delivered on Oct. 2nd by Dr. M. McHugh, who dealt with the threatened outbreaks of bubonic plague. Sir John W. Moore, President of the Royal College of Physicians of Ireland, occupied the chair.

The Belfast Workhouse Children

At a meeting of the Belfast Board of Guardians on Sept. 25th a letter was read from the Local Government Board for Ireland relative to what they term a "fraud" practised for an unascertained period on the children of the workhouse by the abstraction of a large portion of their daily food, and the Local Government Board characterise the action of the officers concerned in allowing such a condition of things to exist as most discreditable. They suggest certain plans to check these "disgraceful irregularities" and they urge upon the guardians the necessity of continuing to use every effort to eradicate the abuses which have crept into the management of the workhouse and are gradually being brought to light, and they consider that the vigilant action of the infirmary committee in discovering the particular fraud referred to is a striking proof of the good results to be anticipated from frequent inspections by intelligent visiting committees It would seem that children who were supposed to get eight ounces of bread were only getting four and a half, and the full allowance of milk was also withheld

Irish University Education.

The Council of the Royal University of Ireland Graduates' Association have issued a statement on the eve of the general election in relation to Irish University education. There are now 5000 graduates of the Royal University who should have considerable influence in guiding public opinion on such a subject and they, as well as graduates of the old Queen's University, are requested to support those candidates who endorse the programme on Irish University education which this association recommends (1) The association objects to sectarian universities; (2) it objects to persons professing any particular religious creed having any special advantages or endowments on that account as contrary to justice and all modern ideas; (3) the association recommends that the affairs of Trinity College, of the University of Dublin, and of the Royal University should be investigated. The examination of the affairs of Trinity College should be conducted (the association recommends) from several points of view: (*a*) As to finances. The authorities of Trinity College refuse, it is said, to give any information on this point. In 1873 Mr. Gladstone estimated the income as £78 000 a year and its expenses as £66,000, and he considered Trinity College the most richly endowed college in Christendom. Owing to reduction in rents and other causes its income has very much shrunk and unless it can effect economies or receive further private or Government aid, it will not be able, according to the published statement of the provost, to provide the costly equipment for modern scientific teaching. So closely are the financial secrets of Trinity College guarded that even now the authorities would not vouch for the accuracy of Mr. Gladstone's figures. It is clear that inquiry is urgently needed. (*b*) As to the educational work it does and has done, and especially as to what extent it has benefited the people of Ireland. Information on this matter of a startling nature is found in the Calendar of Dublin University for 1898, where there are on the roll 4534 voters who may be classified as follows:—Divinity graduates, 2145; medical graduates, 624; arts graduates, 1518; law graduates, 211; music graduates, 34; engineering graduates, 2; total, 4534; which shows that Trinity College is resorted to for professional training and not for education for its own sake. The predominance of divinity is manifest and of these divinity graduates it is curious that while there are 832 in Ireland, there are 1150 in other parts of the United Kingdom; but these figures do not represent the importance of the divinity school, for the greater number of students in that faculty do not proceed to a theological degree in Trinity, but are satisfied with what is known as a testimonium in divinity. For a period of 58 years—from 1840 to 1897—3339 testimoniums were granted; in other words, an average of 57 per annum. (*c*) As to whether Trinity College is sectarian or not. (*d*) As to whether its divinity school should be removed. 4. The Royal University should be placed under suitable representative government like the Victoria University, the London University, and the Birmingham University. 5. There should be an endowment for the Royal University and its colleges proportionate to that of Trinity College and the University of Dublin. In Trinity College there were 1047 students in the year 1899, whereas 2608 students entered for the examinations of the Royal University in the previous year. The numbers for the last year (not yet ascertained) will probably show little difference. In point of numbers the Royal University is of about three times the importance of Dublin University. With a coordination of primary, intermediate, and university education, and the more economic and purposeful use of the large funds of the Intermediate Board, the Royal University and its colleges would have an era of great prosperity in prospect. All these matters must be taken into account in estimating proportionate endowment. 6. If Parliamentary representation of universities continues the Royal University should have two representatives. The following tabular statement showing the university degrees and the residences of the graduates on the electoral roll of the University of Dublin is added to the statement published by the Council of the Royal University of Ireland Graduates' Association:—

—	Divinity	Medicine.	Arts.	Law.
Ireland	832	244	739	118
Other parts of the United Kingdom	1150	290	378	47
Colonies and dependencies.	53	29	45	17
Other countries	76	27	60	7
No address	34	34	296	22
Total	2145	624	1518	211

34 students graduated in music and two in civil engineering, making a grand total of 4534.

Medical Candidates for Parliament.

The following members of the medical profession are candidates for Ulster seats in the Imperial Parliament: Dr. J. King Kerr, J.P. (who is a member of the Belfast City Council), for East Antrim; Dr. E. O. Thompson (surgeon to the Tyrone Infirmary, Omagh), for South Tyrone; Dr. Charles O'Neill of Coatbridge Scotland, for South Armagh; and Dr. O'Connell for East Cavan. Mr. J. Smyth Crone, chairman of the Willesden District Council, who is contesting the Harrow division of Middlesex is an old Belfast Queen's College student.

The Battle of the Clubs at Cork.

The Ancient Order of Foresters have accepted the rules of the medical profession in Cork and their former medical officer, Dr. Giusani, has been duly reinstated. When Dr. Giusani resigned some years ago the number of members in the club was 250. Since then they have had in succession two or three of the imported medical men. Things evidently did not prosper as the membership gradually dwindled, and this once prosperous club can now count not quite 100 members on its books. This remarkable disintegration is steadily going on in other clubs in Cork. Many of the more common-sense members resign and those who remain when threatened with extinction indulge in a process of introspection and discover that the medical men of Cork had much to complain of and that their desire to be paid fair remuneration was only in accordance with what the artisans and working-classes in Cork demanded for themselves.

Oct 2nd.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Reforms in the Management of the Elmira Reformatory.

THE enforced resignation of Mr. Brockway, the distinguished superintendent of the Elmira Reformatory, has attracted public attention to this justly famous institution. An authority on the management of penal institutions states that the superintendent was severely criticised for using a cruel method of corporal punishment—viz., the use of the paddle. But this was not a necessary part of his reformatory scheme. It was rather a personal element which could be omitted without affecting the fundamental principles which he developed. Mr. Brockway was the originator of a new plan of dealing with young criminals in which corporal punishment played only a subordinate part. The Brockway plan was based on the theory that crime is a disease which can be cured in the majority of cases, if the offender is properly dealt with, before the malady becomes chronic. Deterrent penalties are fixed with little regard to their effect on individual criminals. Mr. Brockway's new idea of punishment was to work a reform in the criminal. The aim of the treatment was to be remedial rather than deterrent; penalties should be adapted to individual cases. The best way to protect society, according to this new theory, is to cure criminals instead of merely punishing crimes. This is the theory that Mr. Brockway put into practice in the Elmira Reformatory which he directed for 24 years. The most important devices that he adopted in carrying out his idea are the indeterminate sentence and the parole. The length of the period of confinement depends upon the behaviour of the individual. The inmates are graded according to an elaborate system of marks and credits. [illegible] may secure a parole in 14 months, but [illegible] violation of the rules will detain the offender for the maximum term of his sentence. A paroled person is required to report regularly to a designated officer in the city or town where he resides. If he complies with the requirements he is finally discharged when his parole expires, otherwise he is re-committed. These two devices are the really essential features of the Brockway plan.

Improved Quarantine Regulations.

The extension of the quarantine system of the United States to Cuba has proved the importance of international maritime sanitary regulations. The United States Marine Hospital Service now administers the quarantine of the Cuban ports, and as a result it appears that vessels disinfected in Cuba in accordance with the United States quarantine regulations and receiving a certificate to that effect from the medical officer of the Marine Hospital Service, are, upon arrival at the ports of the United States, considered as having been under observation during the time which has elapsed at sea since disinfection, provided no illness of a suspicious nature has occurred on board, and thus their time of detention at the quarantine stations of the United States is much lessened. This shortening of the time of detention at the ports of the United States has been a great help to commerce, while at the same time the protection to the United States is as great as was afforded under the former methods, or even greater.

The Health of Manila.

Major Guy L. Edie, a surgeon in the United States Army and President of the Board of Health of Manila, Philippine Islands, makes a very interesting report.

Besides the several functions belonging to a board of health in supervising all works and conditions affecting public health the board has general supervision of charitable institutions, prisons, and venereal hospitals and the direct control of the vaccine farm, the municipal chemical and bacteriological laboratories (which the board organised), free dispensaries and hospitals for leprosy, small-pox, and bubonic plague. In matters of vital statistics the board claims accuracy as yet only for its record of mortality. The work of vaccination has made its impress upon the mortality from small-pox. For the nine months from October, 1899, to June, 1900, there were seven deaths from small-pox in the city, while in the month of March, 1899, there were 75 deaths from this disease. The work of vaccination was effected with great difficulty, as the authorities did not consider it advisable to make vaccination compulsory. During the year 622,030 points of vaccine virus were furnished to the army and navy of the United States and to native inhabitants of [illegible] of Manila. In the city [illegible] were effected. The total [illegible] months, October, 1899, to [illegible] of which 3507 were of children under five years of age. The population is variously [illegible] a number averaging about 50 per month occurred in the Chinese quarter, without medical attendance and unreported, some of which were probably due to plague. Only one death occurred from plague among Americans, and that was in the case of a quartermaster's employé. The total number of cases of plague reported was 225, the sufferers in only 58 of which cases recovered. The opinion formed by Major Edie from his experience of the last six months is to the effect that little difficulty will be [illegible] the disease in any intelligent [illegible] sanitary conditions.

Restricting Prostitutes to Certain Districts.

The Supreme Court of the United States has decided in the case of the Church Extension Society *versus* the City of New Orleans that it is unlawful for any public prostitute or woman notoriously abandoned to lewdness to occupy, inhabit, live in, or sleep in any house, room, or closet situate without certain prescribed limits of the city, with a proviso that nothing in the ordinance should be so construed as to authorise any lewd woman to occupy any house, room, or closet in any portion of the city. The question presented to the court was whether one who may own or occupy property in or adjacent to the prescribed limits in the city, whether occupied for a residence or for other purposes, can prevent the enforcement of such an ordinance on the ground that by it his rights under the Federal Constitution are invaded. With nothing in the ordinance to deny the ordinary right of the individual to restrain a private nuisance the court does not consider it one of which complaint could be made by such owners or occupants of property as stated, notwithstanding that the pecuniary value of their property might be depreciated thereby. The management of those vocations which feed upon and minister to human weaknesses, appetites, and passions, the court continues, come directly within the scope of what is known as the police power. Obviously, the regulation of houses of ill-fame and legislation in respect to women of loose character may involve one of three possibilities: (1) absolute prohibition; (2) full freedom in respect to place, coupled with rules of conduct; and (3) a restriction of the location of such houses to certain defined limits. Whatever course of conduct the legislature may adopt is, in a general way conclusive upon all courts, State or Federal. It is no part of the judicial function to determine the wisdom or folly of a regulation by the legislative body in respect to matters of a police nature.

Measurements of School Children

The Chicago Board of Education have established a department called "Child-Study and Pedagogic Investigation" The examination is undertaken for the purpose of determining the mental and physical status of the school-children. Examinations were at first limited to the determination in each pupil of the following points, height, height sitting, weight, ergograph work, strength of grip right and left, hearing right and left, and acuity of vision. In addition to this obvious developmental defects have been noted. The number of children examined down to the present time is 5636. The conclusions thus far reached are that there is a physical [illegible] children are lighter and preco- [illegible] the average child, and that medio- [illegible] with mediocrity of physique. A similar result was obtained in the examination of 33,500 school-children in St. Louis in 1892 by Dr. W. T. Porter. The action of the Chicago Board of Education in establishing this department o [illegible] and physical condition of the [illegible] is the first instance in Amer [illegible] appropriating money for research work and it is a fact which redounds greatly to their credit.

Sept. 18th.

Medical News.

UNIVERSITY OF DURHAM.—At the Convocation held on Sept 22nd the following degrees and diplomas were conferred:—

Doctor in Medicine—Joseph Ellis Baker, M.B, B S Durh., Francis [illegible] *of 15 Years' Standing*)—John [illegible] Edin.; William Henry Crosse, [illegible] Ernest Goddard, M R C S, [illegible] R C S., L R C P. Edin., [illegible] C P, F R C.S Edin., [illegible] Henry Lloyd, M R C S, [illegible], L R C.P., Alexander [illegible], Gordon Fitzherbert [illegible] mas Godfrey Parott, [illegible], M R C S, L R C P, [illegible] S, L.S.A.; Matthew [illegible] A, D P H [illegible] r, M D, B S., B Hy. [illegible], M.B, B S, M R C.S, L R C P.

Bachelor in Medicine [illegible] Reginald Alderson, College of Medicine, Newcastle-upon-Tyne [illegible] for Women; Edward [illegible] Wilfred Burn, College [illegible] Cornell Clapham, [illegible] D Vaz, London Sch [illegible] Ryatt, College of [illegible] London Hospital, [illegible] ham, Frederic Wil [illegible] Atkinson Morland [illegible] Peart, College of M [illegible] Perkins and Claud [illegible] St Bartholomew's [illegible] of Medicine for Wo [illegible] Birmingham; Harc [illegible] pital, Harry Carlil [illegible] Sydney Duke Turn [illegible] Hospital, and Rob [illegible] mew's Hospital.

B [illegible]—Reginald Alderson, College of Medicine, [illegible] m, London School of Medicine [illegible] Frank Wilfred Burn, College [illegible] ell Clapham, [illegible] D'Vaz, London [illegible] att, College of [illegible] ason College, [illegible] Henry Martin, [illegible] M R C S, [illegible] School of Med [illegible] Surgeons, Du [illegible] Newcastle- [illegible] Hospital, College of [illegible] nnerather, [illegible] old Robert [illegible] London [illegible] lth, Mason [illegible] L.R.C P, [illegible] D P H, [illegible] L.R C P., St Bartholomew's Hospital.

Diploma in Public Health (*D P H*)—William Hardcastle, M B, B Hy, M R C S, L R C P.

GUY'S HOSPITAL MEDICAL SCHOOL.—The following Entrance Scholarships and Certificates have been awarded: Senior Science Scholarship for University Students (£50): Mr A R Brailey, Downing College, Cambridge, and Mr S W Cole, Trinity College, Cambridge (equal £25 each), and a Certificate to Mr. D M. Hughes, University College, Cardiff. Junior Scholarships in Science: £150 to Mr. R. W Allen, University College, Auckland; £60 to Mr. C M Wenyon, University College, London; and Certificate to Mr. H Thomas, Kingsholme School, and Mr. F H Lennox-Jones, Latymer Upper School. Entrance Scholarships in Arts: £100 to Mr H. O. Brookhouse, Blackheath School; £50 to Mr. W. H. Dencer, Colfe Grammar School; and Certificates to Mr. G. Cockcroft, Rossall School.

Mr. T. D. Layton, Bradfield College, and Mr. G. F. E. Allison, Rossall School.

UNIVERSITY COLLEGE, LONDON.—The following Scholarships and Exhibitions have been awarded. Medical Entrance Scholarships: Bucknill Scholarship, £30 a year for four years and 55 guineas Scholarship (equally divided), H. T. Mant and W. S. Sweet; 55 guineas Scholarship, H. E. Dyson. Medical Exhibitions: 76 guineas each, C. W. Forsyth and A. M. H. Gray.

CHARING-CROSS HOSPITAL MEDICAL SCHOOL.—The following Entrance Scholarships have been awarded: hip (100 guineas) to Mr. John Heatly Scholarships (each 60 guineas) to Mr. University) and Mr. H. M. Joseph (Cambridge University). Entrance Scholarships have also been awarded to Mr. A. G. Whitaker (40 guineas) and to Mr. Alfred Dinnis (30 guineas).

UNIVERSITY OF CAMBRIDGE.—Dr. L. Humphry has been appointed Assessor to the Regius Professor of Physic for the ensuing year. In his address on resigning office the Vice-Chancellor alluded to the progress made with the plans for the new medical school buildings and to the need for further contributions towards the cost of their erection. The new arrangement with Addenbrooke's Hospital was described as being advantageous alike to that institution and to the university. Rooms for work in clinical pathology, bacteriology, &c., have just been erected by the staff and presented as a gift to the hospital. They will be open for work under the direction of Professor Sims Woodhead during the present term. The open colonnades in front of the hospital, which look south over the grounds, are, by the liberality of Mrs. Peart, to be adapted for open-air treatment.

THE WORSHIPFUL COMPANY OF PLUMBERS.—At the quarterly meeting of the court held at the Guildhall on Sept. 29th Mr. Charles Hudson was sworn into the office of Master, and Mr. Alderman Richard Hind and Alderman Sir John Knill, Bart, were sworn into the offices of Warden and Renter Warden respectively. Dr. F. J. Waldo, medical officer of health of the Temple and St. George's Southwark, and Dr. Reginald Dudfield, medical officer of health of Paddington, were admitted to the freedom and livery of the Company. A copy of a memorial to the Right Honourable A. J. Balfour was laid before the court calling attention to the desirability of the Government dealing with the registration of qualified plumbers in the interest of the public health, and bearing the signatures of Lord Aberdeen, Sir Charles Cameron, medical officer of health of Dublin, the Lord Provost of Aberdeen, Professor W. R. Smith, King's College, London, Professor Matthew Hay, Aberdeen University, and other chief officers of the Congress of the Royal Institute of Public Health held at Aberdeen, and about 600 delegates and members representing sanitary authorities, architects, colleges, hospitals, school boards, and other bodies in various parts of Great Britain and Ireland. It was reported that the following resolutions were passed at the Tenth International Congress of Hygiene and Demography held at Paris:—

1. That all plumbers' work, as much in the supply of drinking water as in the removal of soil or slop water, should be the object of particular attention. The pipes for the distribution of water, as well as the hydraulic apparatus (reservoirs, syphons, &c), and the down pipes for slop water, should be completely protected from frost.

2 That a professional education with a test examination before obtaining a diploma should be demanded of "sanitary plumbers" with a view to spreading among plumbers a knowledge of hygiene and of rational and economic construction in their work.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ARMOUR, DONALD JOHN, B A., M.B. Tor., M.R.C.P. Lond., F.R.C.S. Eng. has been to the Professor of Anatomy, Rush Medical

BARNES, E. G, M.D. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Hartismere District Council.

BURNS, WM. C., M B., Ch B., has been appointed Resident Medical Officer to the Infirmary, Glasgow, vice Inman, resigned.

CHURCH, ANNA L, M.D Irel, has been appointed Medical Superintendent to the Lady Aitchison Hospital, Lahore, Punjaub, vice Miss Beilby, M.D., resigned.

CRABTREE, W., B.Sc. Vict, M.B., Ch.B, has been appointed Medical Officer for the Workhouse of the Stoke-upon-Trent Union, vice C. D. Outred, resigned.

CROSS, FRANCIS RICHARDSON, M.B. Lond., F.R.C.S. Eng., has been appointed Honorary Consulting Ophthalmic Surgeon to the Bristol Royal Infirmary.

DUKE, A. S., L.R.C.P., L.R.C.S. Edin, L.F.P.S. Glasg., has been re-appointed Medical Officer for the Midland Sanitary District of Midhurst.

DURRANT, CHARLES E, L.R.C.P. Lond., M.R.C.S., has been appointed House Physician to the General Lying-in Hospital, York-road, London.

GILLIBRAND, WM., L.R.C.P. Irel, M.R.C S., has been appointed a Medical Referee under the Workmen's Compensation Act, 1897, and to act for Bolton in County Court Circuit No. 5.

GIMSON, K. C., M.B., B.C. Camb., has been appointed Certifying Surgeon under the Factory Acts for the Witham District of Essex.

GRANT, DUNDAS, M.A., M.D., F.R.C.S. Eng., has been appointed Surgeon to the Royal Academy of Music, Tenterden-street, Hanover-square, London.

INGRAM, J, L R.C.P., L.R C.S. Edin., L.F.P.S. Glasg, has been appointed Medical Officer of Health for the Warsop Urban Sanitary District, vice H. Hewer, resigned.

JOYNT, R. L, M.D. Dub, F.R.C S. Irel., has been appointed Surgeon to the Meath Hospital, vice Sir William Stokes, deceased.

MARTIN, ERNEST W., M.B, Ch.B., has been appointed Resident Medical Officer to the City of London Hospital for Diseases of the Chest, Victoria-park, E.

MILLIGAN, W. A., M.A, M.B., C.M., F.R.C.S. Edin., has been appointed Anæsthetist to the Great Northern Central Hospital, Holloway-road, N.

NEWBY, THOS., M D. St. And., M.R.C.S., has been re-appointed Medical Officer of Health for the Cleethorpe Sanitary District.

O'DONOGHUE, J., L R.C.P., L.R.C S. Irel., has been appointed Medical Officer for the Howth Dispensary District, Dublin.

OGILVY, ALEXANDER, B.A., M.D., B Ch., B.A.O. Dub., F.R.C.S. Irel., has been appointed Honorary Ophthalmic Surgeon to the Bristol Royal Infirmary, vice F. Richardson Cross, resigned.

PICKFORD, J. S., L R.C P Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Little Lever District Council.

RHYS, OWEN L, M.B., Ch B Edin., has been appointed Assistant House Physician to the Cardiff Infirmary.

ROSS, R. H., L.R C.P., L R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer to the Whitehead Constabulary, Ireland.

SMITH, H. EMSLIE, M.B, C.M., has been appointed Junior House Surgeon to the Great Northern Central Hospital, Holloway-road, N.

SMITH, W. R, M.D Lond., B.S., L.R.C.P., M.R.C.S., F.R.C S. Eng., has been appointed Medical Officer for the Beeston and Wollaton Sanitary District of the Bosford Union, vice J. Orton, deceased.

SYMES, JOHN ODERY, M D. Lond., M.R.C.S, L.R.C.P., D.P.H. Lond, has been appointed Honorary Physician to the Clergy Daughters' School, Bristol, vice E. Markham Skerritt, resigned.

WATERS, J. F. W., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon and Secretary to the West Norfolk and Lynn Hospital, King's Lynn.

WINDLE, B. C. A, D.Sc. Dub., M.D., has been appointed a Representative on the General Council of Medical Education by the Council of the University of Birmingham.

WINDLE, J. D., M.B, Ch.B. Vict., L.R.C.P. Irel., L.R.C.S. Edin., M.R C.S., has been re-appointed Medical Officer of Health by the Southall-Norwood Urban District Council.

WRIGHT, C. F., M.R.C.S., has been re-appointed Medical Officer for the Rishangles Sanitary District, Hartismere Union.

WRIGHT, H. T., L R.C P., L.R.C.S. Edin., L F.P.S. Glasg., has been appointed Medical Officer for the No. 2 Sanitary District of the Parish of Alston-with Garrigill, vice E. W. Short, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRADFORD ROYAL INFIRMARY.—House Physician for 12 months, unmarried. Salary £100 per annum, with board and residence.

CHILDREN'S HOSPITAL, Nottingham, St. Peter's Church Walk, Nottingham.—House Surgeon (non-resident) for six months. Salary at the rate of £100 per annum

CITY OF LONDON ASYLUM, near Dartford, Kent.—Second Assistant Medical Officer and Pathologist, unmarried. Salary £150 a year, with board (except liquors), furnished apartments, washing, and attendance. Apply to the Clerk to the Visiting Committee, Guildhall, London, E C.

CORPORATION OF BIRMINGHAM CITY FEVER HOSPITAL, Lodge-road.—Second Assistant Medical Officer. Salary £120 per annum, with board, residence, &c

COUNTY ASYLUM, Chester.—Junior Assistant Medical Officer, unmarried. Salary £130 per annum, rising £10 yearly to £160, with board (no liquors), lodging, and washing.

COUNTY ASYLUM, Lancaster.—Assistant Medical Officer. Commencing salary £125 per annum with the usual allowances.

COUNTY BOROUGH OF CROYDON, CROYDON BOROUGH HOSPITAL.—Resident Medical Officer for the Croydon Borough Hospital for Infectious Diseases, for one year. Salary £120 per annum, rising to £140 at the end of six months, with board and residence.

DERBY COUNTY ASYLUM.—Second Assistant Medical Officer. Salary commencing at £110 per annum, rising to £130, with board, lodging, o Medical Superintendent, County Asylum,

Buxton, Derbyshire.—Assistant House per annum, with furnished apartments, board, and washing

FRENCH HOSPITAL AND DISPENSARY, 172, Shaftesbury-avenue, London.—Resident Medical Officer (not a female), speaking French, unmarried. Salary £80 a year, with full board.

[illegible]

[illegible] HULME DISPENSARY (not Provident), Dale-street, Stretford road, [illegible] tments, [illegible] married. [illegible] Assist- [illegible] n, with board, lodging, and washing

KENT COUNTY OPHTHALMIC HOSPITAL, Maidstone.—Surgeon

LONDON TEMPERANCE HOSPITAL, Hampstead road, N.W.—Resident Medical Officer for one year. Salary 100 guineas per annum, with board, lodging, and washing

MACCLESFIELD [illegible] Salary £70 per a[illegible]

MANCHESTER [illegible] House Surgeon [illegible] Salary £77 10s [illegible] rk, [illegible] surgeon to Out- [illegible] Officer Salary [illegible] Council, Rousay, Orkney

PARISH OF SLEAT.—Medical Officer and Public Vaccinator. Salary £100 per annum. Apply to the Clerk to the Parish Council, [illegible]

[illegible] to nurses

SALFORD HOSPITAL.—Junior House Surgeon. Salary £70 per annum, with board and residence.

SCHOOL BOARD FOR LONDON.—Medical Officer for the Board's Training Ship the *Shaftesbury*, which lies off Grays, Essex. Commencing salary £100 a year, which may be increased by £10 annually to £150 a year, with 1s. for each boy examined prior to his admission to the ship. Apply to the acting Clerk to the Managers, School Board Offices, Victoria Embankment, W.C.

STO[illegible] a year, [illegible] coal and [illegible] Apply [illegible] surgeon [illegible] dence. [illegible] surgeon, [illegible] House Surgeon for three months, followed by six months as House Surgeon

WHITBY UNION.—Public Vaccinators for the Whitby Sub-District and the Urban District respectively. Apply to the Clerk to the Guardians, Whitby.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Physician for two years. Salary £100 a year, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS

BIENEMANN.—On Oct. 1st, at Kettlewell, Farnham Royal, Bucks, Margaret, wife of A. J. Bienemann, M.B., of a daughter.

THORNELY.—On Sept. 29th, at 60, Herne-hill, S.E., the wife of William Thornely, M.B., of a son.

MARRIAGES

[illegible] e parish church, Luton, by the [illegible] ne, M.B., C.M., B.Sc., eldest son [illegible] Gateshead-on-Tyne, with Clara [illegible] Mr. and Mrs. Durler, Whitehill, Luton

[illegible] of Frognal, Hampstead, London.

DEATHS.

DUCKET.—On [illegible] Clark A. D[illegible]

LEETE.—On Se[illegible] M.R.C.S., [illegible] aged 33 years.

WOODFORDE.—On July 17th, at Uralla, New South Wales, Alfred Ernest Woodforde, L.R.C.P., L.R.C.S. Edin., second son of W. T. G. Woodforde, M.D., of Oakbank, Spencer's wood, Reading, in his 43rd year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HISTORY OF MEDICAL JOURNALISM IN GREECE.

THE September number of *La Grèce Médicale* contains an interesting article by the editor, Dr. Jean Foustanos of Syra, entitled, Histoire de la Presse Médicale Grecque. Dr. Foustanos says that up to the time of the liberation of Greece, namely in the beginning of the present century, a medical man of education was extremely rare but irregular practitioners abounded. The latter were of two classes—(1) native Greeks who undertook venesection and the management of fractures and dislocations, and (2) the so-called Καλογιατροί ("médecins bons") or Ἰατροὶ τῆς Φραγκιᾶς ("médecins du pays des Francs"), who for the most part came from Italy or the Ionian Islands and wore a fantastic costume which Dr. Foustanos describes, comparing it to that of a Spanish bull fighter. Pouqueville mentions in his history that in one [illegible] in Tripolitza, the chief [illegible] tobacconist from Monti[illegible] course, at this period non-existent, but a very few scientific works were published in Greek, printed at great cost in Italy, and most of them in Venice. Immediately after the liberation of Greece, however, several Greek medical men of education returned to their country from Italy and other parts of Europe. In a few years a certain amount of scientific revival was apparent in Greece; the Medical Society was established in Athens and in 1836 it commenced the publication of the first Greek medical journal, called *Esculape*, after the tutelary deity of the healing art. This journal, unfortunately, had an existence of only three years (1836-1839). Since that period several medical journals have successively appeared but have all been short-lived, the medical men being numerically insufficient to support them. Dr. Foustanos gives in chronological order the following list of medical journals which have up to the present time appeared in Greece. Except in the case of the two last he does not specify the language in which they were published and we therefore reproduce the titles in French as he gives them:—

1836-1839 *Esculape*, Athens, conducted by the Medical Society

1842-1847 *Nouvel Esculape* Athens, conducted by G. Prinaris

1853-1860 *L'Abeille Médicale*, Athens, conducted by A. Gouda

1856. *Esculape* (Second Series), Athens, conducted by A. Anagnostakis, A. Zinnis, and P. Soutzos

1858-1860 *Journal Médical*, Athens, conducted by A. Anagnostakis, and Th. Aphendoulis

1859 *Galien*, Athens

1860 *Le Médecin Populaire*, Athens

1862. *Hippocrate*, Athens, conducted by P. Callivourtzis

1863 *Hippocrate*, Zante

1870 *Esculape*, Athens, conducted by A. Antoniades, G. Karamitzas, S. Manghinas, and A. Georgantas

1871-1873 *Bulletin Pharmaceutique*, Athens

1874. *Almanach, ou Journal Médical et Pharmaceutique*, Athens, conducted by Constantin Delvenis

1874 *Almanach de Santé*, Athens, conducted by A. Diamantopoulos

1879-1897. *Galien*, Athens, conducted by A. Georgantas, N. Maccas, N. Dellaportas, and Skiadaressis, subsequently by J. Bambas, and after him by J. Caravias and several other medical men.

1883-1885 *Journal de la Société d'Hygiène*, Athens, conducted by G. Ch. Vaphas, A. Damberghis, G. Crinos, N. Maccas, B. Patrikios, D. Caterinopoulos, and Ch. Rallis

1884-1885 *Journal Médical Hebdomadaire*, Athens, conducted by A. Callivokas

1884 *Journal Périodique de la Société Pharmaceutique d'Athènes*, Athens.

1885 *Le Progrès de la Médecine des Enfants*, Athens.

1889-1891. *Les Nouveaux Médicaments et les Nouvelles Cures* Athens, conducted by Christovitz

1890-1896. *Journal Médical de l'Armée*, Athens, conducted by Solon Chomatianos, J. Typaldos, and other military medical officers

1895 *Revue Médicale*, Athens, conducted by Rondopoulos

1896. *Hippocrate*, Athens, conducted by Alex. Georgiades

1896 *Progrès Médical*, Syra, conducted by Dr. Jean Foustanos

1898 *La Grèce Médicale* Syra conducted by Dr. Jean Foustanos

Of all the above journals the only ones that survive are the two last named, the *Progrès Médical* (Ἰατρικὴ Πρόοδος), published in Greek, and *La Grèce Médicale*, published in French.

THE DISCRETIONARY POWERS OF CORONERS AS TO HOLDING INQUESTS.

To the Editors of THE LANCET.

SIRS,—I shall be glad to know through the medium of your columns whether it is customary for a coroner to grant a certificate—not, I suppose, of the cause of death, but a certificate which permits the deceased's burial—without any medical evidence having been taken as to the cause of death. The facts on which my query is based are as follows. I was called at 7 A.M. one day to see a woman who had died suddenly the previous night. As I had never seen her during life I told the local policeman to inform the coroner (who lives several miles distant) that I could not grant a certificate. I hear nothing from either policeman or coroner in the way of reply, and when two days afterwards I am in the same district I am told that the woman is to be buried the same day. Hoping you will give me your opinion on this matter for my future guidance,

I am, Sirs, yours faithfully,

Oct. 1st, 1900. NORTHUMBRIA.

⁂ Before giving our opinion upon this case we should like to know whether the woman was buried upon the coroner's order and in what terms it was given. The coroner is to hold an inquiry under the Coroners Act, 1887, when there is reasonable cause to suspect that the deceased "has died a sudden death of which the cause is not known."—ED. L.

"A SINGULAR STORY OF HYPNOTISM."

To the Editors of THE LANCET.

SIRS,—With reference to an extract from a sensational article in the *Daily Mail* on this subject, and which appears in THE LANCET of Sept. 29th (p. 982), I desire to say that it is within the province of any person to enter the out-patient department of any public hospital and to burlesque what he there sees if he feels so inclined. The gentleman who attended at my hospital is a perfect stranger to me, he was courteous and gentlemanly and left expressing an opinion that he had been very interested in what he had seen. He was not there the whole time but had to leave, having an engagement at the office. His remarks, so far as related to Mr. J. May (who is a married man with two children, aged 32 years, and an electrical engineer by trade, and who attends every week at the hospital), were not judicious in their nature and admit of another construction. He apparently took exception to the furnishing of the out-patient department. So long as out-patients have benches to sit down upon and the physicians tables on which to write their prescriptions all is provided which is essential; moreover, the furniture compares very favourably with that found in most larger hospitals. The question of treating disease hypnotically has for many years been under serious consideration. In 1895 at the International Medico-Legal Congress held in New York, of which department I was chairman in the Psychological Section, many papers were read and discussions held on this subject, which was freely ventilated. On my return from the Congress, and after conference with Professor Lombroso of Turin and Dr. Gorodichze of Paris, gentlemen well qualified to form an opinion on its value, I decided to give this treatment a fair trial at my hospital. The success I experienced, especially in cases of static melancholia, folie de doute, neurasthenia, nervous deafness, chorea, and other allied nervous diseases, was of such a nature that I have been induced to continue the same with like results. In nervous cases, in which it is difficult to obtain mental concentration, and consequently direct hypnotism becomes impossible, the suggestion must be made indirectly through a transference medium. This is admitted by the authorities I have previously mentioned. This being one of the varieties of hypnotism, perhaps out of 80 cases which present themselves at the hospital there are only three or four who are so dealt with. The records, however, which I am about to publish will speak for themselves. At the late International Medical Congress at Paris the subject occupied an important position in the discussions, and in THE LANCET of Sept. 29th (p. 974) you give the proceedings before the Congress of Psychology of Paris, in which the department on hypnotism was presided over by Dr. Voisin, physician to the Salpêtrière Hospital of Paris and the leading authority in France on psychology, and you state that after the discussions the members adjourned to witness the cases treated at this hospital and at Dr. Berillon's clinic in the Rue des Arts. I have no doubt in my own mind that amongst the various hypnotic cases shown to the members were cases of transference similar to those alluded to by you. The British Medical Association some years ago formed a committee to investigate the question and many leading specialists in London now send their patients to be so treated by those experienced in its use. The general opinion is that such procedure is legitimate so long as it is carried out by qualified medical practitioners. The hospital, 203, Euston-road, has been visited by physicians, scientists, those interested in the subject, many of whom have witnessed the progress of cases undergoing treatment there. I shall be glad to welcome any person interested in the subject on presentation of his card to the secretary, as the doors are open to all, and any students desirous of witnessing the demonstrations on Thursdays at 6 o'clock will be admitted. There is one remark as to the medium and the question of his being properly hypnotised, I will challenge anyone to wake him by fair means, and shall be prepared to receive any persons you may send for that purpose to the hospital.

I am, Sirs, yours faithfully,

Devonshire-street, W., Oct. 1st, 1900. FORBES WINSLOW.

"MOTOR-CARS FOR MEDICAL MEN."

MR. C. T. W. HIRSCH, M.R.C.S.Eng., L.R.C.P.Lond., Woolwich, has sent us an account of his experiences with a motor-car, from which we extract the following:—"The car I invested in was a Benz Ideal No. 2, with a hood ...... from Messrs. Hewetson's. ...... An instructor was left for a week at the charge of 7s. 6d. a day *plus* his railway fare and meals. I am afraid I did not derive much benefit from him and when I started driving myself I must confess I had a great deal of trouble, the car frequently stopping in the street, due to my not managing the mixture properly. When this was mastered and the regulation of the coils vibrator seen to, the car went splendidly, and in addition to my doing my work in this hilly district I have had some three trips to the South Coast watering places, as well as many daily excursions of from 40 to 60 miles. The machinery on the whole is good. One of the carriage springs broke. ...... A fresh one was supplied but a charge was made for the labour, Messrs. Hewetson supplying a new spring gratuitously. The tyre on one wheel became loose, due to the wire breaking. This was also mended gratuitously, though the agent charged for the time he spent and the expenses incurred in taking the wheel to the maker's. The only other trouble of import was that the bush on the second speed loose pulley became worn, and as a result the pulley was not quite true and occasionally gripped the true pulley, and when this driving on another speed a loud noise, violent vibration, and pulling up of the machine occurred. The wearing of the bush was said to be my own fault, as though I kept the grease-box well filled the hole in the lower part must in some way have been blocked. ...... Messrs. Hewetson ...... tell me that a car has run 35,000 miles without requiring attention. I am afraid *I cannot say the same for mine.* Motor-cars certainly are very useful but liable to get out of order, and I question whether I would buy one again with my present experience. ......"

A POINT UNDER THE WORKMEN'S COMPENSATION ACT.

To the Editors of THE LANCET.

SIRS,—Will you kindly inform me whether it is necessary for a medical man to insure his groom against accidents under the Workmen's Compensation Act? I am, Sirs, yours faithfully,

Oct. 2nd, 1900. SUBSCRIBER.

⁂ Employers are not liable for servants under the Workmen's Compensation Act, 1897, but it is a question whether they will not be liable under the extension of the Act to agricultural labourers; when the duties of the servant are to attend to animals certainly a medical man in the country would be liable, and it is in any case wiser to insure, as this can be done for a few shillings.—ED. L.

AN IMPROVED CYCLE SADDLE.

WE have received from Messrs. T. Dunlop and Co. of 20, Beulah-hill S.E., a specimen of their improved Henson cycle saddle. The Henson saddle, which is of the pneumatic variety, is so constructed that there are two separate pads, with a space between them and a depression in the centre of each pad to receive the ischial tuberosities. This form of saddle is found to be very comfortable and convenient by many riders and for many it is, indeed, one of the best forms of cycle saddles. It, however, requires a little perseverence to become used to it, especially by those who have hitherto ridden a peaked saddle. In order to meet this inconvenience a peak has been added to the Henson saddle which can be removed at the option of the rider. We have tried this saddle and have found it to possess the advantages claimed for it.

THE RIGHT TO SUE FOR FEES.

To the Editors of THE LANCET.

SIRS,—I hold the M.R.C.S. Eng. and the L.R.C.P. Lond. qualifications and want to know if I can sue a patient for professional attendance and medicines. I think I can as I know a brother medico who holds the Edinburgh qualifications who is constantly putting people in the county court, but I have been *told* by an L.S.A. that it is necessary to have that qualification in order to sue for medicines supplied. I should therefore be much obliged for an authoritative statement from you on the subject. I am, Sirs, yours faithfully,

Oct. 1st, 1900. SUBSCRIBER.

⁂ It is not necessary to hold the L.S.A. If our correspondent was qualified and registered before 1887 he is entitled by Section 31 of the Medical Act of 1858 to practise according to his qualifications and to demand and recover in any court of law ...... reasonable charges for professional aid, advice, and visits and the cost of any medicines .... rendered or supplied by him to his patient. If registered after 1887 he may practise medicine, surgery, and midwifery and recover in course of law expenses for medicaments (Medical Act, 1886, Section 6). An exception is made under both these Acts as to Fellows or Members of a College of Physicians.—ED. L.

THE MOUNTING OF MUSEUM SPECIMENS.

To the Editors of THE LANCET.

SIRS,—Will any of your readers kindly inform me of any literature giving a full description of the modern methods followed in the preservation and mounting of museum specimens.

I am, Sirs, yours faithfully,

Oct. 2nd, 1900. F. A. W.

PERIPHERAL NEURITIS.

To the Editors of THE LANCET.

SIRS,—Will any of your contributors oblige me by stating where and under what title I may order the latest literature on the subject of peripheral neuritis? Thanking you in advance,

I am, Sirs, yours faithfully,

Oct. 3rd, 1900. MEDICUS.

ERRATUM.—In our last week's issue in the list of books received from Messrs. J. & A. Churchill "The Theory and Practice of Medicine", should read "The Theory and Practice of *Hygiene*."

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS

note that only those subscriptions he Proprietors of THE LANCET W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid; and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.	
One Year	£1 12 6
Six Months	0 16 3
Three Months	0 8 2

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

During the week marked copies of the following newspapers have been received: *Cambrian, Derbyshire Times, Stockport Advertiser, Portsmouth Times, Birkenhead News, Gloucester Journal, Birmingham Daily Post, Gloucester Herald, Daily Nation (Dublin), Manchester Evening Chronicle, Sheffield Independent, Leeds Mercury, Citizen, Scotsman, Times of India Pioneer Mail, Liverpool Daily Post, Architect Builder Bristol Mercury, South Wales Daily News, Yorkshire Post, Lowestoft Standard, Ceylon Standard, Health, Madras Standard, Perth Courier, Manchester Guardian, Engineer and Iron Trades Advertiser, Christian, Aberystwyth Observer, Farm and Home Sanitary Record, League Journal, Bath Herald, Hastings News, Reading Mercury, Abingdon Herald, Hertfordshire Mercury, City Press, Westminster Gazette, Local Government Chronicle, Mining Journal, Ilford Guardian, Local Government Journal, Surrey Advertiser, Essex Weekly News, Flintshire Observer, Horse Guards Gazette, The Sun, Weekly Irish Times, Woodbridge Reporter, Grocer's Journal, Caterham Free Press, Seaford Journal, Bayswater Chronicle, Surbiton Times, Thirsk News, Cornish Times, Peterborough Standard, Weekly Free Press and Aberdeen Herald, Coventry Times, Braintree Advertiser, Dorking Advertiser, Glamorgan Free Press, West London Observer, Eastern Daily Press, &c., &c.*

suddenly the previous night As I had never seen her during life I told the local policeman to inform the coroner (who lives several miles distant) that I could not grant a certificate. I hear nothing from either policeman or coroner in the way of reply, and when two days afterwards I am in the same district I am told that the woman is to be buried the same day. Hoping you will give me your opinion on this matter for my future guidance, I am, Sirs, yours faithfully,

Oct. 1st, 1900. NORTHUMBRIA.

*** Before giving our opinion upon this case we should like to know whether the woman was buried upon the coroner's order and in what terms it was given. The coroner is to hold an inquiry under the Coroners Act, 1887, when there is reasonable cause to suspect that the deceased "has died a sudden death of which the cause is not known."—ED. L.

"A SINGULAR STORY OF HYPNOTISM."

To the Editors of THE LANCET.

SIRS,—With reference to an extract from a sensational article in the *Daily Mail* on this subject, and which appears in THE LANCET of Sept 29th (p. 932), I desire to say that it is within the province of any person to enter the out-patient department of any public hospital and to burlesque what he there sees if he feels so inclined. The gentleman who attended at my hospital is a perfect stranger to me, he was courteous and gentlemanly and left expressing an opinion that he had been very interested in what he had seen. He was not there the whole time but had to leave, having an engagement at the office. His remarks, so far as related to Mr. J. EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C , are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months . ..	0 16 3	Six Months	0 17 4

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

An Introductory Address

Delivered at the Commencement of the Winter Session of the Faculty of Medicine of the University College of South Wales and Monmouthshire on Oct. 10th, 1900,

BY SIR JOHN WILLIAMS, BART., M.D., F.R.C.P. LOND, &c.,

CONSULTING PHYSICIAN TO THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN, WATERLOO ROAD; CONSULTING OBSTETRIC PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, ETC.

GENTLEMEN,—When the Dean of the Faculty of Medicine honoured me with an invitation to open the session of this college I accepted it with pleasure He informed me that it would be my duty to deliver a short address to the students, and more especially to those of them who are devoted to the study of medicine. These students I heartily congratulate upon their selection of a profession. There are some *worse professions, but there are few better, and to him who* loves the work there are none better. Whatever the social rank, whatever the dignity, whatever the rewards of the profession, it possesses unquestionably one good thing, and that is hard work. From the day upon which you enter upon the special study of medicine to the day when you will lay aside the stethoscope and the thermometer your life will be full of hard and interesting work. You will have work, some with payment, some without payment; some with abundant gratitude, some with none. You will receive much that you will not deserve, both of praise and blame, but the distribution of the two, however unwisely or unjustly each be awarded, will be, perhaps, on the whole, not far from being a fair measure of your due.

That the treatment of the profession and the estimate of its work by the public are often unjust can hardly be questioned, and who can wonder at it when we bear in mind the usual education imparted in our schools and universities? By education is generally meant the study of books and of ancient literature, while nature and its laws, life with the forces which act upon it and the circumstances in which it develops and those in which it fades are disregarded. The elementary facts upon which science is built are considered as scarcely worthy of attention. They are treated as if they had but little concern with life and none with learning and scholarship. The result is that ignorance prevails [illegible] hich govern our life and actions. [illegible] in the upper as well as in the lower classes of society, and ignorance and superstition in respect of medicine, of the power of drugs, and of the skill of medical men are as prevalent among the educated as they are among the uneducated classes "Christian Science," with its claim to cure all diseases by ignoring them, flourishes most among the upper classes. Here it appears in gorgeous colours accompanied with the sound of trumpets, while at the other end of society it is found presenting a humble but obstinate front in the coroner's court or before the police magistrate in the persons of its loyal devotees known as the "Peculiar People." Besides these immaterial means of curing diseases such as inflammation, paralysis, toothache, tuberculosis, and cancer, there are a countless number of undiscovered drugs, known only to their proprietors and the officers of the Patent Office, which for good reasons are not made known to the public, each of which, according to the proprietors of, and believers in, these panaceas, has performed marvels in preventing and curing diseases, known and unknown, fatal and not fatal—indeed, it matters not of what nature, for all diseases, it is said, are cured by these undiscovered drugs. The astonishing fact is that any disease remains to afflict the human frame.

You ask me where I obtain these extraordinary facts. I reply: Look at any newspaper, daily or weekly, English or Welsh, religious or secular (among the latter, however, there are some notable exceptions) and you will find all that I have stated. You [illegible] sible cures and s [illegible] which everyone possessed of the most elementary knowledge of the laws of health and of the processes which take place in the living body knows to be entirely devoid of foundation. Nevertheless, these statements are published broadcast, day by day and week by week, in newspapers which profess to teach and to lead the public and to form public opinion. These newspapers are the property of men who hold more or less influential positions and are respected in the country. They are edited, some by clergymen, some by ministers, and some by laymen. The statements which I have referred to are sanctioned, by silence, in speech, or in writing, by all concerned in the publication of these journals. They occasionally contain testimonials to the wonderful virtues of the advertised drug, and these emanate from all manner of men, some of whom are probably, like the historical camel, evolved in a garret, while others hold positions and make professions which would lead one to expect that they would not be guilty of attaching their names to, or be a party to publishing, anything for the truth of which they could not vouch. Now and again a bard in a frenzy of inspiration pours forth in rhythmic or alliterative measure the wondrous works of quackery and the miracles of ignorance When I find the religious newspapers of the Principality besmeared with such advertisements as I have referred to, some of them not only false but foul and wicked, I cannot help feeling the blush of shame as I bear in mind under whose ægis they are published The faithful, finding them in their weekly guide, accept them without question and act upon them as truths tested by the standard, sanctioned by their party oracles and sealed with their approval. How long will this continue? So long as the practice will pay the manufacturer and purveyor? Is it not possible to cause the purveyor at least to realise the character of the material to which he forms the conduit from the manufacturer to the purchaser? If this be not possible then the remedy must and will be found in the education which, if not now, will by-and-by be given in our schools. Let the elements of science, the laws of growth and decay, and the laws regulating the functions of the living body be taught in our schools and our young men and young women will themselves be able to estimate this mephitic rubbish at its proper value.

Meanwhile, however, and notwithstanding what I have [illegible] upon the choice of a pro- [illegible] l an ennobling one. The [illegible] in which you will be placed [illegible] to foster in you, if not the graces and polish of society, yet those qualities which are usually admired—sometimes laughed at—but never laughed at either by rich or poor when they are the victims of suffering and disease—and these afflictions come to poor and rich alike To poverty and pain, suffering and sorrow, disease and death you will pay your daily visits Your work will be on the dark side of life—not seductive, is it?—but this will enlarge and widen your sympathies (not of the frothy sentimental variety), whet your wit, increase your resources, and humanise you through and through. Yes, gloomy as the prospect appears, you are to be congratulated, provided you are made of the stuff of which good doctors are made.

Now, what are the qualities which are necessary for the exercise of a profession whose work is such as I have indicated? They are many, but I shall be able to refer to two or three of them only. Some of them are gained only after a long training and large experience—"knowledge comes but wisdom lingers"—while others should be possessed from birth or acquired in early life. Of the latter the first is health—a sane mind in a healthy body. To the boy destined for the medical profession good health is essential—in the first place to enable him to bear the physical and mental strain made upon him by the training through which he will have to pass in order to qualify, and in the second place by the physical demands and mental anxiety arising from practice Success in medicine, as in some other professions, means survivorship, and survivorship usually means a good physique A man with feeble health may be a great preacher, a great lawyer (though I can hardly imagine him to be a great pleader), a great writer, or a great scientist, but he cannot be a great medical practitioner, for disease and suffering recognise no office time or any day of eight hours. The medical man must be ever ready and ever active and must know no fatigue. But I hear you say, "Health is inherited, a sound constitution cannot be acquired." This is true in a great degree, and a lad of feeble health would do wisely to eschew the profession of medicine. It is, however, also true, that good health may be destroyed, that bad health may be made good, and that a feeble constitution may be strengthened, especially during the period of childhood, boyhood, and early manhood.

Some years ago elementary schools were not so numerous in the country, or perhaps so efficient in some respects, as they are now. I cannot vouch for the accuracy of the latter part of the statement, for I am speaking of that happy time, for schoolmasters as well as for boys, which preceded the period of periodical inspections and payment by results. For the reason which I have mentioned children had to walk to school from one to three miles in the morning and home again in the evening, carrying with them their midday meal. To accomplish this distance a boy took from an hour and a half to two hours in the morning. He reached the schoolroom at 9 o'clock and was supposed to work until 12 o'clock. Then followed a relaxation from work lasting two hours, a few minutes of which was occupied in partaking of a very simple meal, but a meal which was consumed with a relish and an enjoyment which many a luxurious epicure would give all but his dinner to possess. This meal, frugal as it was, was ample for the child's requirements. Then came the great pleasure of the day, hockey, football, or hare and hounds (cricket was unknown in country schools in those days), than which no exercises, games, or gymnastics are better calculated to develop all the organs of the body in a healthy manner. Thoroughly refreshed but untouched by fatigue the boy entered school again at 2 o'clock and remained until 4 o'clock. Then came the journey home, which occupied in winter at least two or three hours and in summer from three to four, with all its delightful incidents, unbeclouded by the thought of a home task—a new imposition condemned by every healthy-minded boy. The boy never took the straight path (boys never do) or the shortest route. His curiosity, his inclination, his spontaneous energy, call it what you will, led him to deviate to the right and to the left from the normal course. He, moreover, required amusement and play after his exhausting labours in the schoolroom. There were various objects of interest which had to be visited on the way home. In a pool a mile up the stream on the left was the old trout, which had to be tickled or presented with various cunningly-devised invitations to land, to which his wariness never condescended to reply. On the right was the track of a hare. This had to be carefully inspected, while the discovery of a gin was a source of intense enjoyment and the division of its string afforded a doubly exquisite pleasure, for it ensured "puss" a free run and baulked the cunning and skilful poacher in his nefarious designs. Then the nest of an old crow upon a high and solitary tree should not be forgotten. It was some distance off, it is true, but it demanded a daily visit in the spring of the year, and the strongest and bravest boys climbed up in turn to inspect and count the eggs and in the end generally to rob the nest. This would sometimes lead to a falling out—an event which is said to happen not rarely among thieves, but in this instance the honest bird did not come by its own. The encounter took some time to come to an issue. Unfortunately the morning told the story of the evening and this led to the application of the appropriate but unpleasant remedy. This old remedy has now gone out of fashion. Some of you may have known such delightful school-days, while others may have not, but may from early days have been subjected to the dull continuous grind which is productive of a precocious and showy but feeble mind, coupled with a body one would not accept as a gift. Such a boyhood as that which I have described braces mind and body, strengthens weak frames, and makes healthy youths. I confess that I look back upon this period in my life, not only as one of the pleasantest and brightest, but also as one of the best spent, for its effects have been my mainstay during the rest of my career. As so much may be done during boyhood and early youth to establish health and to lay in a store of strength which will serve your turn through life, I would urge you to seize opportunities for physical exercise, for I imagine that during your sojourn here these opportunities will be abundant. When you shall have left Cardiff and have gone for your further training to London or elsewhere you will find such opportunities scanty by reason of the fuller employment of your time as well as the distance of your lodging from the green fields.

The training of a lad for the profession of medicine cannot be begun too early, and particular attention should be paid in his case to that part of education which should, in a greater or less degree, be the possession of every youth whatever his position in life when he leaves school—the training of his senses. All boys should be trained to use their eyes, their ears, and their hands—for it may be said of many, "They have eyes but they see not, and ears they have but they hear not"—and to acquire manual dexterity. Every lad should be taught early to use his eyes, to see and recognise the various objects, living and dead, which nature so bountifully supplies in earth, air, and water. To a medical man this training is of special importance, for the faculty of observing is one of his chief aids. Without it he is helpless, he is not fit to visit or to treat the sick. The cultivation of this sense cannot be begun too early. I will illustrate its value, not from a professional visit to the sick-room, but from an entirely different phase of life.

A party were once upon a coursing expedition, but their wanderings in search of the hare had proved fruitless. Like incompetent craftsmen who blame their tools they blamed the land and the farmer, for they had come to the conclusion that there was no game on the land and that the farmer was a poacher. Disappointed and despairing of sport they were on the point of giving up the search when a man approached who was known to one of their number as an accomplished poacher. He said to the new-comer, "Dafydd, swllt am scwarnog." "Yn wir?" queried Dafydd; "cewch, yn wir," was the reply. Satisfied as to the ability and willingness of the would-be sportsmen to pay the shilling Dafydd walked quietly around and in a few minutes the cheery cry of "See-ho" fell on delighted ears. The hare was coursed and caught, thanks to the dogs and the cultured Dafydd. "Swllt am un arall," and in a short time the same pleasant cry was heard again. This illustrates well enough the difference between the trained and the untrained physician when visiting the sick-room. The sportsmen with the untrained eyes had walked over the land the whole day and had seen nothing, while the poacher, whose delight in the daytime and on shining nights had been the study of "puss" and her habits, whose eyes had been trained from boyhood to discover her on her form and to watch her on her quiet or hurried rambles or gambolling with her mate in the light of the queen of night, readily and surely discovered her hiding-place. The experienced and cultured physician, in like manner, when he visits the sick-room sees at a glance those visible signs which reveal the past and lift the veil which hides the future, while the untrained man sees nothing and learns nothing—to him the past remains a blank and the future hidden.

Again, every child should be taught to use his ears and his hands. Singing is in some degree taught in most schools; drawing, with some amount of handicraft, might also be taught with great advantage. Children are taught to play on the violin, harp, or piano from early years. A small fiddle is obtained for the little fingers which cannot stretch over the stops of the finger-board of the full-sized instrument. It is only by beginning his training at an early age that one becomes an accomplished performer on one of these instruments. A touch, a stretch, a strength of finger, and a certainty are thus acquired which cannot be gained in later life. The ear also is trained to distinguish and appreciate sounds in their tone, pitch, volume, and character. By training the hands a manual dexterity with a delicate sense of touch capable of appreciating slight vibrations and slight differences of resistance and elasticity are acquired, all of which are of the greatest value to the practitioner in the diagnosis and treatment of disease. A trained hand can often by palpating the chest alone discover the seat and sometimes the nature of disease, while its use in the diagnosis of disease in other cavities is constantly called into requisition. A trained ear, again, is of no less importance in the detection and appreciation of the various sounds which are produced in the different organs of the body both in health and disease, and it renders possible a diagnosis of the nature, seat, and extent of diseases which would not be possible without its aid. Training of the eyes and hands is as essential to a medical man as it is to an artist, and training of the ears and hands is as necessary to him as it is to a violinist or a pianist The education in elementary schools should be a training and not a cramming, such as it is apt to become when estimated by so-called results. It should be a training calculated to help a lad to live a better, a happier, and a more intelligent life in whatever station he be placed. It should be the same for all. No difference should be made between the education of the son of the labourer, or the son of the farmer, of the parson, or of the medical man.

To the delightful pursuits I have mentioned [illegible] added, when the lad has passed to a higher [illegible] others of a different character. Books will the[illegible] chief, although perhaps not his only, study. It becomes a question whether in these schools a difference should be made in the education of youths destined for different callings in life—whether that of one should be on ancient lines and that of another on modern lines, that of one classical and that of another scientific, or that of one literary and that of another commercial. It is still held by some that the best preparation for all professions is a classical education, but the more general opinion is that a difference should be made and that other subjects should be taught in addition to Greek and Latin. In many of our schools there is an ancient side and a modern side, and boys destined for certain pursuits are placed in the former while others who intend to follow other vocations are placed in the latter. For all, however, for whatever calling they are destined, a certain general training is given. The subject, however, which is of interest and of importance to you is what is the best, or at least the best attainable, general training, the best attainable culture, for a boy who prepares for the study of medicine. The answer to this, made long ago and partially acted upon to this day, is a classical training. This answer, however, should be reconsidered in the altered state of [illegible] lad's time is devoted [illegible] ages and to making [illegible] was for centuries the [illegible] and it was also the language of theology and science. At a later period the discovery [illegible] in Lati[illegible] Church [illegible] comparatively recent times. In these two languages, after the revival of learning in Western Europe, was enshrined practically all learning. Greek and Latin became known as [illegible] learned languages. I have not a word to say against classical scholarship, but there is much to be said upon the question whether a boy preparing for the medical profession should devote several years to acquire a knowledge of the two languages. The training for the three professions of theology, law, and medicine is in many respects much alike. There is a special training for each, but before this is entered upon a course of general training has to be passed to fit every candidate for admission to either of the three—for the pursuit of his special studies. For the three professions this general training is, and always has been, much the sam[illegible] The preparatory tr[illegible] of Greek and Latin [illegible] pursued in the higher [illegible]ty. When the university course is finished the aspiring cleric, in the best arranged schemes, enters a school of divinity to study his special department of learning for two years before he obtains a licence to practise his profession. In the case of the clergyman the whole course of his education, from the time he enters a higher school, is a preparation, a special preparation—as special a preparation for the study of his special subject as the study of science is for the special study of medicine. In the case of the law the preparatory studies are the same as those for theology, a knowledge of Latin being essential to a learned lawyer.

What is the value of a knowledge of Greek and Latin to a professor of the art of medicine? I will tell you in the words of a distinguished writer and scholar who has recently passed away: "As to doctors, can we gravely admit that they ought to understand the language in which their prescriptions are written, and that they find it instructive to read Galen and Hippocrates in Greek? To men of science it is pointed out that their ever increasing technical terminology is systematically formed from Greek and Latin words. This is true: and it is also true that a man of science might obtain a perfect grasp of this terminology by means of a list of words that he would learn in a day and the use of a dictionary that he might acquire in a week." Although useless to the medical man in his profession, however, yet it may be necessary to know Greek and Latin in [illegible] these two languages. I will let the same writer reply again: "*The fact* is that the study of Latin (for Greek, except in respect of scientific terminology, has much less to *do* with the *question*, and would hardly have been placed on a par with Latin here but for the hasty and random way *in which* the stock arguments on the question are continually repeated) cannot tell us what the English language is; it can *only help us* to understand *how* it has come to be what it is. In order to learn to speak English with accuracy and precision we have but one rule to follow—to pay strict attention to usage." But it is said, "If we *do not* teach a boy Latin or Greek we cut him off from the highest literary enjoyment, and we prevent him from developing his taste by studying the best models. It would avail little to call in question (had I space and inclination *to do so*) the surpassing excellence of ancient literature. For my purpose I must regard this point as decided by an overwhelming majority of persons of culture. But it will not be denied that in the English, French, and German languages there is a sufficiency of good literature to fill the leisure of a person engaged in any active calling, a sufficiency of work calculated to give a high kind of enjoyment and to cultivate very adequately the literary taste. And if such a person was ever visited by a painful hankering after the time-honoured volumes that were sealed to him, he might console himself by taking note how often his contemporaries who had enjoyed a complete classical education were in the habit of taking down these masterpieces from their shelves. For I cannot help thinking that classical literature, in spite of its enormous prestige, has very little attraction for the mass of even cultivated persons at the present day. I wish statistics could be obtained of the amount of Greek and Latin read in any year except for professional purposes, even by those who have gone through a complete classical curriculum. From the information that I have been able privately to obtain I incline to think that such statistics, when compared with the fervent admiration with which we all speak of the classics upon every opportunity, would be rather startling." The fact seems to be that, with comparatively rare exceptions—and those are not in the professions—a classical education is pursued not for the culture which it gives but in order to acquire the instruments for special pursuits in after life, such as theology, law, philology, history, archæology, the profession of teaching, &c. Those who prepare for such pursuits specialise from the first, for they devote themselves from the beginning of their education to gain command of the instruments with which they work in after life, while those devoted to science are made to learn that which is of little or no use to them in their after-pursuits. For the latter and to a lad destined for the medical profession matters at present are still worse, for what command does he acquire over the Greek and Latin languages? Greek is not now compulsory, while the knowledge of Latin demanded of the medical student is so small that it does not enable him to read the easiest Latin book except with difficulty and with the aid of a dictionary. The time—a part of six or seven years—devoted to gain such an accomplishment appears to be wasted. What, then, should a boy destined for medicine learn before he begins his special studies at the age of 17 or 18 years? I should say that in addition to those subjects which are generally taught in schools he should have a thorough course of the English language and literature. This will do more to train his intellectual faculties, to give him a command of language, a vocabulary, a taste for good literature, and a culture far larger and better than he can obtain by acquiring an elementary knowledge of Latin, which will be of no use to him, is too scrappy to be a source of intellectual enjoyment, and which will in a short time be forgotten. French and German should also be learned, and I believe the power of reading both languages with ease could be acquired in the time now devoted to learning Greek and Latin. A knowledge of these two modern languages is essential to a practitioner who is desirous of being among the leaders of his profession, for the work done in the laboratories and hospitals of France and of Germany is of such a high order that no one who is ignorant of it can be considered abreast of medical knowledge.

There are, however, some among you who are fortunate enough to have another accomplishment—a knowledge of the

Welsh language. You should study it with the same care and minuteness as you study English, or as you would study Greek and Latin were you devoted to classical pursuits. In the time which you now devote to Latin and Greek you would acquire a thorough knowledge of this ancient tongue. I am not in a position to compare or contrast the value of Celtic with that of classical studies—your professor of the Welsh language might do that for you—but there are certain distinct advantages to you in the study of Welsh over the study of the dead languages. You already possess a more or less large vocabulary of the language; you can speak it; you know its idioms; your ear has been trained to its accentuation, the inflexions of its vowels, and the mutations of its initial consonants. A knowledge of its grammar can be gained without much difficulty. Prose composition will prove a pleasant and improving pastime, and if verse-writing be of any value in education you may indulge in it with at least the feeling that you know the material in which you are working and that you are not arranging words of whose meaning you have no full appreciation in a form of which you have still less. The alliterative *pedwar mesur ar hugain*, together with the numerous rhyming measures in the language, will give you an ample field for the exercise of your vocabulary and for the display of your skill in polishing sentences. Translations from English into Welsh, and from Welsh into English, and from French and German into English and Welsh will further add to your linguistic skill and give you accuracy in the use of words. The Welsh language, moreover, will introduce you to a valuable and interesting literature, unknown to, and unappreciated by, our neighbours between Offa's Dyke and the German Ocean, while it is the subject of study to scholars in Western Europe. As a means of culture the language and literature of Wales have not been duly appreciated in England, or, indeed, in the Principality itself. Some years ago a request was made to the Senate of the University of London that Welsh as well as French and German should be recognised as a voluntary subject in the matriculation examination. Together with others I wrote to some members of the Senate stating the reasons why I thought that that body should accede to the request. Among those reasons were: (1) that a number of the candidates for the matriculation examination were Welsh lads many of whom habitually spoke Welsh while some did not speak English until they were 13 or 14 years of age; (2) that the whole of the examination was conducted in a language foreign to these lads; and (3) that consequently they laboured under a great disadvantage when compared with English candidates especially and even when compared with French and German candidates, for although English was a foreign language to French and German boys each could select his own language as a voluntary subject. One of the members who appeared to take some interest in the subject replied by asking, "Where are examiners to be found?" The foundation of the Welsh University has removed this inequality, and the Welsh boy may now study his native tongue with the feeling that his knowledge of Welsh language and literature will receive due recognition in the schools of the university.

The course of instruction which I have indicated will, under the circumstances in which you are placed, and especially by reason of the limit of time which you can devote to general subjects, do far more for you than a fragmentary knowledge of Greek and Latin. It will develop your intellectual faculties, it will furnish you with a large store of linguistic and other knowledge, and it will introduce you to the best literature and the highest culture. It will, moreover, place you in the best position to begin and continue your professional studies, it will enable you to follow the progress of medicine in after life, and it will furnish you with an inexhaustible store of intellectual enjoyment from which you will be able to draw at will in the leisure hours of your active life. While, however, you pursue these general studies a part of your time should be devoted to acquire an elementary knowledge of the natural sciences so that when you go to college you may be prepared to enter upon those studies which bear directly upon your profession. You should possess an elementary knowledge of the principles of physics, chemistry, and biology, have a grasp of the general character of science, and be disciplined more or less in the methods of all sciences, so that in your first year at college you may be able to take full advantage of the means of study there afforded to you. There you will pursue the study of anatomy, physiology, and chemistry which will fit you for your further studies in the wards of the hospital. Facts will be pointed out to you and you will have to find and see them for yourselves; their relations and classifications will be indicated to you and you will have to verify them; your minds will be trained in scientific methods. This will occupy the first three years of the curriculum, and then, if you have been diligent, you will pass on to the supreme stage—the study of medicine. In the wards of the hospital you will have to study disease in its relations its causes, its onset, its course, its terminations, its prevention, and its treatment. You will not only be required to see and to realise what is pointed out to you but you will also be required to learn how to see and discover for yourselves, to observe symptoms, to discover signs, to classify them and reason upon them—work in which not only your trained intellect but also your trained senses will be called into full exercise. If you shall have availed yourselves of the opportunities of learning offered you during the three years you will have passed in college you will find your knowledge of disease and your skill in detecting its seat and nature grow apace. Most of your time will be spent in the out-patient rooms or in the wards, performing your duties as clerks or dressers or attending the physicians and surgeons on their daily visits. You should, however, not be satisfied with discharging the merely obligatory portion of your hospital duties. It is said that the best way to know a man is to live with him. It is equally true that the best way to know disease is to live with it, to reside in hospital; and it should therefore be the aim of each one of you to hold a resident post as house physician, house surgeon, resident obstetric officer, either one or all. Such a post will give you in a few months an amount and a kind of experience that private practice will not furnish. It will give you opportunities to watch the progress of disease from hour to hour, to observe closely its features, follow its fatal footsteps, or hail the amelioration of its severity under the treatment administered and the restoration of the patient. Moreover, you will be working under the eye of your master physician or surgeon; you will be required to "get up your case" fully and thoroughly and to record its progress from day to day. This will implant in you careful and methodical habits which are invaluable in the practice of medicine.

There are a few more words I should like to say. You should cultivate independence of character and freedom of thought. The two generally go together and both will be essential to you in the practice of your profession—both for your own comfort and for the good of your patients. The curriculum which you will pass through will tend to foster these qualities and your experience in hospital and in practice will tend to strengthen them. Tradition has no authority in medicine. I have already referred to the ignorance of science and its methods which prevails generally. Ignorance is rarely modest or doubting; it is dogmatic and credulous. You will find it often a source of great annoyance to yourselves and of infinite mischief to your patients. For your own happiness you should cultivate that absolute indifference to the chatterings of incompetence which is based upon a thorough knowledge of your profession, a complete grasp of your cases, and a rigid adherence, undeflected by outside considerations and influences, to the evidences of your senses and the dictates of your reason.

From the day on which you enter the hospital until your course is finished, the circumstances in which you will be placed and the influences under which you will work will arouse in you the feeling of humanity and foster its growth and development. It is scarcely possible for you to walk the hospital without becoming infected with the contagion of sympathy, but the sympathy is not of that variety which evaporates in sentimental speeches on platforms and finds its reward in publicity. It is of more lasting stuff. It is not the sort which shows itself in cries of impotence in the presence of difficulties and flees from the presence of suffering. The sympathy which will be yours is at its best in the presence of suffering and danger. These serve but to strengthen it. It is not a sympathy for fine days and holidays, processions, and public meetings; its work is amidst the storms of life; there is no place for it amidst the frivolities. It seems as if asleep or dead when there is no work for it; it is aroused only by the call of distress, to which its response is never wanting, and when aroused it is always to some purpose. I cannot illustrate this better than with the old story of the man who had fallen among thieves. There he lay by the roadside, stripped, robbed, beaten, wounded, bleeding, unable to cry for help, and left half dead. By chance a wealthy and a holy man came down that way and when he saw the sufferer he passed by on the other side; and likewise another who came and looked upon him and passed by on the other side. Lastly, a man with an ass came where he was, and when he saw him he had compassion on him and went to him and bound up his wounds, pouring in oil and wine (the antiseptics and healing drugs of the period), and set him on his own beast and took him to an inn (the nursing home of the day) and took care of him. I verily believe that this good man must have been a doctor. I know of no finer example of that sympathy of which I speak and which you should not fail to cultivate.

An Address

ON

SOME PROBLEMS OF TROPICAL MEDICINE.

Delivered at the London School of Tropical Medicine on Oct. 3rd, 1900,

BY SIR WILLIAM MACGREGOR, K.C.M.G., C.B., M.D. ABERD., D.Sc., LL.D., &c.

GENTLEMEN,—When in compliance with the request of Dr. Patrick Manson I consented to deliver to-day the opening address to the students of this School of Tropical Medicine, I felt that I was committing myself to a task really beyond my powers. This feeling was deepened on glancing over the formidable syllabus of lectures and demonstrations to be given by the teaching staff. The ground to be covered is so vast, the subjects to be dealt with are so very important, the extensive and diversified knowledge required both in teacher and student is so deep and so wide, as to make one's own ignorance painfully apparent to oneself. I therefore find comfort in the fact that I am here to-night because I am an administrator, not because I am a doctor of medicine.

I understand that the objects of this school are to convey to its students a special acquaintance with the diseases that are of most frequent occurrence in tropical regions and to train them for the investigation of such maladies on systematic and scientific lines There is excellent reason for believing that Her Majesty's Secretary of State for the Colonies took very seriously to heart the deplorable mortality among public officers and others in our more unhealthy tropical possessions. The calling into being of this school is but one of the many means devised or fostered by the Right Honourable Joseph Chamberlain for curtailing the death-roll of our fellow-citizens in those insalubrious over-sea territories of the empire. This school is but one link in the chain, and the chain is already a long one and it promises to be continuous.

THE TRAINING OF COLONIAL MEDICAL OFFICERS.

The leading idea of the school, therefore, is the appropriate training of colonial medical officers. It is, however, to be hoped that others may take advantage of it and that it may add another ring to the ever-widening stem of the already gigantic tree of medical knowledge. It is certain that there are a great many people in this country at the present moment suffering from what are usually called "tropical diseases," and that these sufferers are not, and cannot be, attended by medical men who have had tropical experience Very many of these patients must come under treatment by the ordinary medical practitioner. Cases could be adduced in which some of the most distinguished men in the medical profession in this country have been completely at sea as to the exact nature of certain tropical diseases and their sequelæ. The teaching supplied by such a school as this should be a useful addition to medical men practising in this country, especially if cases of tropical diseases in sufficient numbers can be made available to them for clinical study. The list of students who have passed through the courses since Oct 1st, 1899, does not show, however, that the school is patronised by the British medical practitioner. Taking into account the already immense and still growing traffic and the rapid and steadily accelerated communication between this country and the tropics, and bearing also in mind the intolerance of any form of quarantine in the United Kingdom, the probabilities are that the special study o[illegible] be more and more forced u[illegible] this country, either by the systematic study of such maladies at the ordinary schools of medicine or at specific institutions such as this. If this branch of medicine is neglected, then the sufferer from the tropics will be a certain loser, but not always the only one.

At the present moment, however, many of us are very specially interested in this school in relation to the medical services of our more unhealthy tropical colonies. It is probably the case that not a few of those who have so far passed through this institution were already familiar with many tropical diseases, knew them by experience, and understood how to treat them. To students of that category the clinical studies of these maladies here is not nearly so important as is the training to be had to fit them to investigate tropical diseases on the spot, on the most advanced systems known to medical science and with a full knowledge of what has already been done in these matters in this country and elsewhere Any average medical officer who has sufficient training in making investigations of this kind will soon master the practical details of all tropical diseases in his district, provided that he is given time, the necessary instruments, and proper accommodation. The best and most proper place for making such researches is undoubtedly the tropics themselves. It must be patent to every person who thinks at all on the subject that the training of medical officers to carry out investigations of this kind is of the utmost importance to each colony, to the empire, and to humanity at large. We all know, or ought to know, what has been done in this field by such men as my late highly esteemed friend Dr. Bancroft of Brisbane; by the distinguished Dr. Patrick Manson, the inspiring genius of this school; by the father of Strachan's disease, the present chief medical officer of Lagos; and by many others who have practised medicine in the tropics. These men had no specialised opportunities given them; they had not the advantage of any systematic training such as is offered now at this school. We are therefore justified in expecting a great deal from the younger men who now come forward here to learn at once the most suitable and the most advanced methods of conducting original investigations in the great and rich tropical field

STATE ENCOURAGEMENT OF MEDICAL RESEARCH.

But I can tell you that this training and preparation will not yield all that we are justified in expecting from it without the cooperation of the Secretary of State for the Colonies and of colonial administrators. The trained medical officer must have time and opportunity granted to him That the Colonial Secretary will in every possible way encourage and suitably recognise the researches of medical officers may safely be taken as granted. It is, however, at times a very difficult matter for an administrator so to arrange service affairs as to be able to grant to medical officers the time so necessary to carry on scientific investigations of this kind without their being submitted to grave or destructive interruptions. Colonial administrators and others in high authority have not always in the past lent to the head of the medical department the support required by him. They have not always given to their chief medical officer the confidence that Alexander the Great extended to his I was myself very fortunate in the first new country in which I served in having as chiefs such enlightened men as Lord Stanmore and Sir William des Vœux Whatever was really required for the new medical service in Fiji was granted. As one result of that there is no doubt that at the present moment the chief medical officer of that colony, Mr. Glanvill Corney, is thoroughly familiar with the practical aspect of every disease met with in that country. Many other colonies have been less fortunate, but if that is so now Mr Chamberlain, who not only thoroughly understands the value of medical work but also takes the deepest interest in it and has done more than any other person ever did before to popularise scientific medicine, is just the man to see that medical matters are put right wherever they are wrong. They are, in my humble opinion, wrong where original work cannot be done. My own personal experience has been that the most unhealthy colonies are, or were, those in which medical research was most neglected; that, however, is apparently being remedied everywhere. In Lagos, for example, no fewer than 10 full equipments for medical officers of the scientific type have been provided by the Secretary of State for the Colonies. An excellent laboratory has been built and an analytical chemist has been appointed. This has been done there without any reference to any school of tropical medicine, and would have been carried out precisely the same had there been no such institution and no medical commission in existence. We look, however, to this school now, as a means of better enabling our medical officers to take advantage of the opportunities that will henceforth be given to them in Lagos, and no doubt similarly in other colonies, for you may depend upon it that colonial administrators will know their duty sufficiently well to follow with zeal the course that has been taken by Mr. Chamberlain. Moreover, there is at the present time in this and other countries a volume and force of public opinion behind sanitary and medical work that has, perhaps, been dormant from the days of Moses and Machaon till now. It was only the other day that the celebrated Grassi lectured on malaria before the Queen of one of the Great Powers of Europe. Such an event is redolent of the times.

It is not my intention to occupy your time in speaking of the details of your training for the investigation of disease, beyond emphasising their very great importance. I would rather in a familiar way give those of you who have not yet practised in the tropics some idea of the extremely interesting and very important work that awaits you there.

OLD DISEASES AND NEW RACES.

You will still, for example, have many opportunities, especially in new countries, of acquiring valuable information respecting the original or natural location of disease, the landmarks of which are fast diappearing before modern civilisation. You will see how old diseases are being communicated to new people and you will be able to watch the strange results that are thus produced. You will doubtless be in a position to add much to the existing knowledge of tropical diseases already more or less studied, and you will in all probability be able to establish the existence of maladies at present unknown and unrecognised; you will thus reduce the sum of human suffering. Can any man desire greater glory than this? As different forms of disease were localised originally, and still remain more or less so, it follows that the experience of tropical medical officers differs largely according to country. Their opportunities are therefore diversified in an unusual degree. Perhaps I may personally have had exceptionally good opportunities of assisting—as a French writer observed some time ago—at the dissemination of disease among new races.

TYPHOID FEVER.

The late Sir Thomas Watson was very anxious to know whether typhoid fever was known in Polynesia. From inquiries made there in 1875 it appeared certain that this disease did not occur in the islands. In 1875, however, a case was observed in a gentleman recently arrived from Australia. It assumed the virulent form that is accompanied by petechial spots, and the patient died. Soon after this a case occurred in a European in the mountains of Viti Levu. The disease, it appeared, had been contracted in the locality where the first case was treated. Sporadic cases were met with at intervals, but they were, formerly at least, few in number. Perhaps their scarcity was largely due to the fact that houses were supplied by rain-water collected from the roof and stored in metal tanks. There was, however, a form of continued fever in Fiji that very accurately simulated typhoid fever up to the ninth day, when it suddenly culminated and the patient got well in a very few days Typhoid fever was also unknown in British New Guinea. In that country the continued fever that in Fiji so closely resembled typhoid fever was not met with. Typhoid fever is also absent in West Africa. It would appear to be a by-product of civilisation, which is perhaps also true of cancer, diphtheritis, and some other diseases. Fiji, by the mere fact of becoming occupied by a considerable number of Europeans, was a centre for the distribution of other diseases to her neighbours; but she sometimes received their maladies in return, as will be seen from what follows. The disease of yaws has been from time immemorial endemic in Polynesia If a Fijian child escapes yaws terrible results are expected to the future health of a being so abnormally constituted. Yaws represented our measles, scarlet fever, chicken-pox, diphtheritis, and whooping-cough in one.

YAWS.

The probability is that no medical officer will be long in the tropics before he is brought into contact with yaws. This disease, like most others in the torrid zone, is of course parasitic. I first met with it in the Seychelles Islands in African slave-children liberated there by our cruisers and indentured as plantation labourers. It is curious that this disease is much more mild in the African and the Papuan races than it is in the Polynesian race. It may be that it is newer to the latter. In the African it is sometimes so ill-marked that only a medical practitioner of some experience can recognise it at first sight. It is not very contagious to Europeans, but when caught it is loathsome and troublesome. I have never looked on yaws as a disease that could be cured under from three to six months.

I was once invited by my superiors to take up the extermination of this disease in New Guinea, but being then the only medical man in a colony larger than Great Britain, and having absolutely no means of dealing with an endemic contagious malady, I was obliged to say, in somewhat different words, that I might as well try to arrest an earthquake. In Polynesia, if not in New Guinea, there is not only the endemic nature of the disease to contend against but also the very strong native prejudice of "the conscientious objector" in its favour—a prejudice difficult to deal with, though the disease is not made an object of worship there as is the case with small-pox in West Africa.

Though yaws was indigenous to Fiji, tinea imbricata was not known in that colony till introduced by plantation labourers. Many Line Islanders were brought to Fiji as plantation hands, and among them tinea imbricata is endemic, whilst yaws was unknown to them. The Fijian gave yaws to the Line Islander, and the latter gave his loathsome tinea to the Fijian. The Solomon Island recruit also brought tinea imbricata to Fiji with him, and he in turn left the colony, in a great many cases, with venereal disease in some form or other.

VENEREAL DISEASE.

Venereal disease was not known to the Pacific Islanders, or to the Papuans, till it was taken to them by Europeans Certain social habits of these peoples facilitated the rapid spread of these maladies, and they flourished with the usual luxuriance of a crop on new soil. It was very extraordinary how the Pacific Islander was affected by soft chancre. Very frequently the sore developed into a great spongy mass that bled profusely if touched. In not a few cases the ulceration caused death by penetrating the abdominal wall. These specific sores were also remarkably contagious. On the other hand, syphilis, being more slow in its processes, did not immediately effect the ravages that might have been expected. Gonorrhœa was all but incurable in native women. At first many of them were brought to Fiji as plantation hands. It was extremely rare that one returned home with a child. The trader had some small share in spreading these diseases, but it was insignificant compared to what was done by the labour traffic. Yet in the face of all this some good Churchmen, and at least one bishop, who visited the recruiting islands expressed themselves as favourable to the labour traffic. These good men did not see behind the calico—"Come storpiato è Maometto."

MEASLES.

Fiji was also the centre for the distribution of measles in 1874, a disease introduced there by one of Her Majesty's ships of war. The epidemic that followed destroyed between a third and a fourth of the whole population, affording a striking example of the exuberance of a new disease among a new people. In this respect, however, measles was not more surprising in Fiji than was the usually insignificant disease of itch in British New Guinea. This latter malady, which was introduced in some old clothes, sped like a tidal wave along the coast, and in a few weeks thousands of people were covered from head to foot by the most exaggerated form of the disease. It probably spread much faster from the fact that one shirt might be worn by several people in one day. When matters were beginning to assume a somewhat serious aspect, the disease, having spent itself, [illegible] declined to the level it will prob[illegible]mmunity where clothes are common [illegible] the human face.

DYSENTERY.

There are few scourges that require the same thorough [illegible] study which dysentery calls for. This disease, [illegible]tagious forms, was unknown in [illegible] a score of years ago. In recent years it has caused many deaths there. It began in Fiji with the advent of a European population and led to con[illegible], even before annexation, [illegible]asles, and frequently after[illegible]orm. From the first intro[illegible]as regarded as contagious. [illegible] established and the houses [illegible] rain-water stored in metal tanks dysentery among them became much rarer, but on large plantations and in native villages it took on at times a very malignant form. Instances occurred in which even 50 and 75 per cent. of the Polynesian labourers on an estate died from this disease, which was new to them. Excessively high mortality from the same cause occurred also on some of the Queensland plantations among the Polynesians employed there. I was once received at a certain plantation by an interesting-looking boy of about 14 years of age, who was evidently not of the usual class of recruits. On being asked who he was, he said he was So-and-So from New Britain. To the question, "How many are there of you?" he replied, "Plenty all die, only me." I found that there had been 115 of them and that he was the sole survivor. This was the work of dysentery. The treatment in each epidemic was at first like groping in the dark. In a very deadly outbreak that occurred amongst some three score of recruits landed out of a vessel in which they had been battened down for 30 hours during a hurricane, an examination of the contents of the intestines of those who had been dead but an hour or two showed that these consisted of a mass of what were then called vibrios. In consequence of this observation a mixture of corrosive sublimate was given to the two score survivors, all in hospital. The remedy acted like a charm [illegible] But this remedy failed [illegible] elsewhere in the [illegible] acted with extra[illegible] be of any use. [illegible] It appeared that dysentery is made up of entirely different diseases or of one disease that presents widely diverse stages It offers a splendid field to the humanitarian and to the enthusiastic scientist who we trust may be sent out from this school. Were I to judge from my own personal experience I should say that dysentery causes more deaths than any other disease in tropical countries. No other malady is so universally distributed and of such constant occurrence.

Laveran says, "Le paludisme est certainement la plus répandue des maladies endémiques," and Dr. Patrick Manson says of malaria, "It is the great disease of the tropics." My experience is different. I have served in two countries where there was no malaria; never in one where people did not die from dysentery. Last year of 39 cases of dysentery treated in Lagos Hospital 10 died, say one in four; of 128 cases of malarial fever, four died, one in 32. Dysentery is the chief agent in the rapid depopulation of the Pacific. It swells the death rate in West Africa, but not so much amongst Europeans as amongst natives. But there one does not see the wholesale depopulation from this disease that is sometimes so clearly observed on a Pacific island from the return [illegible] dysentery. [illegible] house fly as an active agent in its spread in plantation hospitals and took precautions accordingly. The communicability of this disease has always to be taken into account in the tropics, more particularly in places like West Africa, [illegible] of houses often flows into the [illegible]ouses have been built and out [illegible] their water. [illegible]ut an effective and practical means of dealing with contagious dysentery will be the greatest benefactor of the races that live in the tropics. He may claim to be the saviour of the Pacific Islander, the most loveable man of men now living. It is a study that I most earnestly commend to your attention and on which I trust you will all turn the searchlight of science. Dysentery is a destructive giant, compared to which strong drink is a mere phantom.

MALARIA.

To the tropical European, though perhaps not to the tropical native, the most important study is probably that of malarial fever, the investigation of which has already furnished us with some of the finest examples of human intelligence, perseverance, and observation, and unveiled to us some of the most wonderful of the workings of nature. To myself this chain of marvels, full of poetry and religion, nowhere better seen than in the splendid illustrations of Major Ross, I.M.S., and Dr. Fielding Ould, always recall the words of the second greatest Teuton of the century:—

> [illegible]

The prediction that malarial fever would be found to be due to a parasite having its cycle in man and the mosquito, is fit to be compared with Goodrick's theory of the cycle of Algol, with Leverrier's and Adams's assigned position of Neptune, and with Murchison's prediction of gold in Australia To my own mind it recalls the early teaching of the germ theory of antiseptics by the immortal Lister. It may not improbably lead to an equally great revolution in medicine The position assigned by foreign writers to our British scientists in this, the greatest of recent discoveries, is, and must remain, most honourable to them and to our nation. The name of Dr. Manson, one of the brilliant lights of this institution, will always be connected with the fertile hypothesis that has led to the astounding revelations of that prince of observers, the great Ross, of Grassi, Celli, Bignami, Bastianelli, Koch, and others.

The whole subject of malarial fever is of more importance to the Italians and to ourselves than to any other nation. The Italians have, they say, 11,000,000 of their people exposed to it, which, according to Celli, furnishes them with 2,000,000 cases a year, with an average mortality of 15,000. It is true that it is almost unknown in Great Britain itself, but Laveran states: "Morehead estimait qu'aux Indes les fièvres palustres comptaient pour 40 sur 100 dans la mortalité générale." This is probably not proved. Dr. Manson at the Royal Colonial Institute showed what a serious matter malaria is on the West Coast of Africa This is enough to demonstrate of what vast national importance it is to the British Empire.

There seems to be some tendency at the present time to seek the origin of malarial fever in coloured tropical children. Surely it must be acknowledged to be an old domesticated disease in the United Kingdom and on the continent of Europe, for which aboriginal children could not at any time have been held responsible. You all remember how in the beginning of this century the anopheles completely routed one of the most powerful British armies ever sent to the continent of Europe Then, again, our history supplies few more pathetically ridiculous pictures than the kingly founder of the Royal Society dodging his medical advisers to take his Peruvian bark on the sly. Of course, Dr. Schwalbe would say at once that the king contracted his fever abroad. As the two chief attacks occurred 19 and 20 years after His Majesty "came to his own," the probabilities are strong that he owed them to the genuine domestic English anopheles.

In these modern investigations into malaria the Italians have nobly done their share; so have the Germans, through the illustrious Koch. We owe, further, a very great debt to Laveran. I have often been asked by non-medical friends, who has done this great work? whether it is all British? It appears to me to be more or less like this: Manson was the surveyor, Laveran made the road, Ross built the bridges and laid the rails, and Grassi, Bastianelli, Bignami, and Celli provided the rolling-stock. Grassi says: "Preciso perciò che la scoperta che gli anofeli inoculano la malaria umana è uscita dal mio cervello, seguendo una via da me ideata. Naturalmente anche la mia scoperta, come moltissime altre, non sta isolata, ed io non ho mai esitato a dichiarare che sono pervenuto ad essa giovandomi della ipotesi dei mosquitos svolta tra gli altri da Laveran, Manson, &c." Angelo Celli writes: "Sotto i consigli del Manson, cioè del celebre parassitologo che aveva gia descritta la vita della filaria nel corpo delle zanzare, il case the sufferer had lived as Europeans live. In West Africa there are, however, very marked cases of destructive lupus.

Tetanus.

An equally remarkable experience was met with as regards tetanus. In the disturbances that took place in Fiji in 1876 and 1877, when the mountain chiefs refused to recognise the authority of the Queen and Lord Stanmore had to reduce them to obedience by force of arms and without any army, we treated about 150 wounded men suffering from all kinds of injury. Although the nursing and dressing must have been very imperfect, and operations were performed under difficulty, there was not a single case of tetanus. On the other hand, an officer who had received very serious injuries from the explosion of a charge of dynamite in the interior of British New Guinea died from true traumatic tetanus. He was camped at the upper end of the alluvial country on a piece of ground cleared by us close to the foot of the hills, some 60 miles from the sea Four or five days later, after a journey down the river, during which we camped each night on its alluvial bank, he was got on board the steamer and a few days thereafter showed the unmistakeable symptoms of tetanus. He was taken straight to the Cooktown Hospital and died there from this disease. No case of tetanus in man or animal had ever been heard of before in British New Guinea. It is not clear that the case of Commodore Goodenough, who was reported to have died from tetanus from an arrow wound received at Vanikoro, is parallel to this one. It is quite possible that the detachable bone point used by Papuans and some Micronesians on the tips of their arrows may in his case have been left in the wound and have caused septic poisoning. These bone points, prepared by scraping down a piece of human bone, would contain septic matter, yet I have not known these to produce tetanus in New Guinea. It may here be mentioned that erysipelas was unknown in those countries.

Tinea Imbricata.

The steady stealthy progress made by new invading disease was well seen in British New Guinea in the case of tinea imbricata. It was a domesticated disease in the west, on the Fly River for example, where it is known by the same name that is applied to tobacco. It was also domesticated in the east end, where it is called by a word that in a certain district means "to curl" or "fold up" The central district was still free from it as recently as 10 or 12 years ago, but it is slowly and surely gaining on that region, and during the last three or four years cases have been appearing even at Port Moresby. In a few years it will be endemic over the entire coast, a great eastern wave from the Line and Solomon Islands meeting a wave equally great and irresistible coming from the west. There, as in Fiji, the best treatment was found to be fumigation with sulphur, but it is not possible to apply the remedy universally in New Guinea so as to extinguish the disease.

Other Tropical Diseases.

I can only mention by name several other tropical diseases which I have met with that are of special interest and that require investigation. There can be no doubt that ankylostomiasis is indigenous in the Pacific. In 1876 it was found in Fijian mountaineers and in recruits from the Solomon Islands. Perhaps some of you may be able some day to explain its wide distribution and its exact significance. Cerebro-spinal meningitis was not a native disease but it appeared amongst Indian coolies in Fiji. How it came there was a mystery. Beri-beri was not, I believe, a Fijian malady, but it has been introduced by plantation labourers from Japan. In New Guinea it is indigenous but not common.

In New Guinea there is a curious multiple tumour often met with as large as a walnut. It occurs most frequently about the elbows or the parts of the body that touch the ground when one is asleep on it. This has not been investigated It is probably parasitic. In the Pacific there is a strange post-mortem appearance that is extremely common and that I trust some of you may throw light on. In the hilum of the kidney there is very often half a teaspoonful of brown or purulent fluid. It is found in the greater number of bodies even if dead only an hour or two Its cause or origin, so far as I know, has not been made out.

Rabies and "Dingoes."

As an example of the kind of medical legislation as to which you will have to give advice I may first cite from my own experience with rabies. As you all know, there is a species of dog, the so-called "dingo," native to Australia and New Guinea Where that animal came from is not clear. My distinguished friend Professor Giglioli of Florence gives good reasons for regarding the Australian aborigines as degenerated Aryans. If they are so they probably brought their dogs with them, and this at a time when rabies did not exist in Aryan communities. We shall not consider here whether the barking of dogs is a modern accomplishment or whether the dingo gradually forgot the art. The dingo and the dog cross readily and the first cross between them barks. Doubtless, therefore, the dingo would be readily susceptible to rabies There is a wild dingo on the top of the Owen Stanley range in British New Guinea, and a complete specimen was secured and deposited by me in the Queensland Museum, but the result of its examination is not yet known to me. The domestic dingo is very common in New Guinea as a pet, as a hunter, and as a table delicacy. All the dingoes of a village meet several times a day to howl and they never separate without a fight. They are provided with long, thin, sharp teeth, which they use in season and out of season, but by preference when out of sight. It closely resembles, or is identical with, the Australian dingo. I have never seen a native dingo in the Pacific Islands. The point that most concerns us here is that the Australian and New Guinea dingoes were free from rabies. The Australian colonies have protected themselves from rabies by instituting a term of quarantine on imported dogs. It was seen that rabies introduced into a country like New Guinea with swarms of ill-tempered biting dingoes, among a bare-footed, bare-legged population, and with a wild dingo in the mountains and numberless pigs everywhere, would be a very serious matter not only for that country but also for the whole of Australasia. The matter, therefore, was dealt with on the broadest platform. A representation was made to the great colonies that had charged themselves with part of the burden of maintaining British New Guinea, urging that the Secretary of State for the Colonies should try to induce France, Germany, and Holland to introduce laws similar to those of British New Guinea to prevent the introduction of rabies into their possessions in those seas. The then Prime Minister of Queensland, Sir Samuel Griffith, saw at once the importance of the measure and warmly supported it; it was, I believe, also approved by the Government of New South Wales. The then head of the Government of Victoria thought the proposal more or less ridiculous and was of opinion that France and Germany would give no attention to such a trifle. Lord Knutsford and Lord Salisbury, however, obtained at once the cordial coöperation of the three foreign Governments There is, therefore, good reason for hoping that now the whole of Australasia is, with reasonable care, secured for all time against the terrible disease of hydrophobia.

The "Jigger."

The question of the introduction of the "jigger" is one that has recently occupied the attention of the Indian Government. To such matters even as the control and distribution of this flea you require to devote time and study. Guided by our experience in Lagos we could only report to the Colonial Secretary that the "jigger" does not cause any noticeable inconvenience on official expeditions, and that it appears in private life to claim very little attention. But a medical officer advising his Government in India would require to know a great deal about the insect before he could venture to recommend any legislative steps regarding it or could suggest that no action whatever should be taken.

Leprosy.

It is probably now generally conceded that the disease of leprosy is communicable and that the isolation of lepers should be carried out in the interests of the community. No aboriginal people whom I have known have ever entertained the slightest doubt as to the contagious nature of the disease. The natives of West Africa isolate the lepers. In the South Seas they kept them apart and often buried them alive when they reached an advanced stage of the disease. More than 20 years ago I read in a German author that leprosy was extinguished in Scotland "durch die Entmannung der Manner" I have not been able to find the authority for that statement, the author of which has been dead for many years. Leprosy was at one time apparently not uncommon in Scotland. In the "L'Histoire Universelle" of M. Rambaud it is stated that Scotland's most celebrated king died from this dread disease. The whole subject of leprosy now requires to be studied exhaustively in the light of the new pathology. No doubt some of you are aware that the native Fijian treatment was to bake the sufferer from leprosy near a slow fire It [illegible] were cured in that way. [illegible] hether a fuller knowledge [illegible] ation of such a cure.

QUARANTINE.

I would call your attention for a moment to a medico-legal subject of great importance to many colonies and to which I trust some passing attention may be given in the courses of this school. I allude to quarantine against the introduction of infectious or contagious disease. In all international conferences on quarantine matters British delegates take their stand against the imposition of quarantine. Their system is the isolation of affected or suspected individuals, the disinfection of vessels, and sometimes of cargo. This procedure can be carried out successfully only in a country where there are [illegible] sanitary services. [illegible] where patients an[illegible] it needs a staff [illegible] to exercise surve[illegible] been exposed to possible contagion, and it requires the means of dealing with any of these wherever he may be found. Here in the United Kingdom cleansing and disinfecting can be carried out with scientific accuracy and completeness and at small cost. In this country, then, in the face of the drainage, the [illegible] to suspected persons, and the [illegible] e as well as with infected perso[illegible] nay not at any time become necessary. But it is widely different in most colonies. Here the outer line of defence, imposing quarantine on infected or suspected vessels or persons, becomes a necessity. You will find that it will tax your powers to the utmost to advise your Governments how best to combine the public safety with the minimum of disturbance to trade, for that in practice is the problem to solve. At Lagos we have tried to combine the two systems by providing the medical department with the powers necessary to protect us from outside by imposing quarantine on arrivals and to exercise surveillance ashore over persons exposed to a possible infection but who cannot, or need not, b[illegible]. Ashore, the medical officers may [illegible] and isolate, an infected individual; [illegible] a village, or a district in quarant[illegible] strength of the staff available, the inadequacy of accommodation, the evil sanitary condition of a[illegible] a great and populous area, make [illegible] that we should depend entirely, or [illegible] line of defence against epidemic disease. You are perhaps aware that in Australia a system [illegible] been in force for several years. Th[illegible] the Australian continent is very [illegible] action, [illegible] er and inner ri[illegible] isease. The wh[illegible] erious study at your hands.

WATER AS A CARRIER OF INFECTION.

Let me impress upon you the extreme desirableness of becoming experts in the examination of water. Nothing is of greater importance in the tropics. Although the new doctrine of malarial fever shows that water is only an indirect agent in the production of that disease it still remains an essential factor in its continuation and spread. It retains all its former importance in respect of other diseases In West Africa the medical officer should be able to say whether a given well is safe or not on account, for example, of guinea-worm. Water is popularly credited with the origin of the "craw-craw" disease in Europeans. It doubtless has much to do with the spread of dysentery, typhoid fever where that exists, cholera, and several other maladies. Altogether it is one of those subjects to which you cannot give too much attention. Personally I have always contended that the quality of the water used by a community may have as much, or nearly as much, influence on them as has the quality of the food which they eat or of the air which they breathe A medical officer is constantly liable to be asked by his Government to report fully on the water-supply of some place or of some community.

CONCLUDING REMARKS.

I cannot conclude these somewhat dry and disjointed remarks without offering my hearty congratulations to you who are to become students at this school. In my opinion your lot is the most enviable of any body of men in this great country. You have already travelled over the ordinary road of medical education and have become acquainted with the more frequented parts of the limitless field in which you are to labour. You have become ordinary members of the greatest, the most beneficent, and therefore the noblest of all professions. It can be said with greater truth to-day than it could 3000 years ago: Ἰητρος γὰρ ἀνὴρ πολλῶν ἀντάξιος ἀνδρων. Here you are now to be taken into some of the by-paths of medical study. There you will be brought face to face with some of the most interesting problems of science, questions which are of vast importance to the life and health of the individual and which will exert a reflex action that will be felt in many of the transactions of public, of national, and even of international life. I trust and hope that you will leave this school well fitted by your knowledge of your profession to do your part in the exercise of your calling, and that you will have securely planted in your mind that high sense of duty that is the life and soul of religion, of patriotism, and of every efficient public service, and that enables the medical man to devote by instinct, and unselfishly, all his mind and all his strength to the prevention and cure of every disease that affects humanity.

Presidential Address

ON

THE ROMANCE OF SURGERY.

Delivered at the Inaugural Meeting of the 128th Session of the Medical Society of London on Oct. 8th, 1900,

BY JOHN H. MORGAN, M.A. OXON., F.R.C.S. ENG.,

SURGEON TO CHARING CROSS HOSPITAL AND CONSULTING SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

GENTLEMEN,—When it was announced to me that by the kind suffrages of the Fellows of this ancient society I had been elected to the important and honourable position of your president it was not without considerable apprehension that I accepted the position which was offered. For it could not but be felt that to follow in the footsteps of so many distinguished men as have occupied this chair would be a task of no small difficulty. I was, however, reassured by a knowledge of the fact that the loyalty of the Fellows of the Medical Society is so thorough and so well proven, that throughout my year of office I could rest secure of the support and assistance of one and all in my efforts to make this society a focus for earnest work amongst all classes of the profession. I have read with interest and profit the addresses which have been delivered from this chair for the last several years, and so many and so instructive are they that to choose a fresh topic was by no means an easy matter. Following the example of [illegible] h me on a holiday excursion. [illegible] me in journeys over Europe [illegible] or from Warsaw to Cadiz: Or I might have transported you with me to the barrens of Newfoundland or the woods of Nova Scotia, and although I could not have interested you with a disquisition on the flora that we found together I might have treated you to some observations on the fauna of those wild countries, particularly those which lend themselves to pursuit with the rod, the rifle, or the gun and have told you many things which are not to be found in works on medicine or surgery as means of diagnosing the age of a hoof mark or the direction of your camp Indeed, it has often occurred to me that there are the materials for a most instructive lecture on the cultivation of the powers of observation which is entailed by many forms of sport and the powers of inductive reasoning thereby engendered. We have only to read Baden Powell's hints on scouting to see how many things we neglect to observe in our daily life, whilst their application has been delightfully pointed out by a member of our own profession in the varied experiences of Sherlock Holmes.

But we have returned from our holidays, refreshed and case the sufferer had lived as Europeans live. In West Africa there are, however, very marked cases of destructive lupus.

Tetanus.

An equally remarkable experience was met with as regards tetanus. In the disturbances that took place in Fiji in 1876 and 1877, when the mountain chiefs refused to recognise the authority of the Queen and Lord Stanmore had to reduce them to obedience by force of arms and without any army, we treated about 150 wounded men suffering from all kinds of injury. Although the nursing and dressing must have been very imperfect, and operations were performed under difficulty, there was not a single case of tetanus. On the other hand, an officer who had received very serious injuries from the explosion of a charge of dynamite in the interior of British New Guinea died from true traumatic tetanus. He was camped at the upper end of the alluvial country on a piece of ground cleared by us close to the foot of the hills, some 60 miles from the sea Four or five days later, after a journey down the river, during which we camped each night on its alluvial bank, he was got on board the steamer and a few days thereafter showed the unmistakeable symptoms of tetanus. He was taken straight to the Cooktown Hospital and died there from this disease. No case of tetanus in man or animal had ever been heard of before in British New Guinea. It is not clear that the case of Commodore Goodenough, who was reported to have died from tetanus from an arrow wound received at Vanikoro, is parallel to this one. It is quite possible that the detachable bone point used by Papuans and some Micronesians on the tips of their arrows may in his case have been left in the wound and have caused septic poisoning. These bone points, prepared by scraping down a piece of human bone, would contain septic matter, yet I have not known these to produce tetanus in New Guinea. It may here be mentioned that erysipelas was unknown in those countries.

Tinea Imbricata.

The steady stealthy progress made by new invading disease was well seen in British New Guinea in the case of tinea imbricata. It was a domesticated disease in the west, on the Fly River for example, where it is known by the same name that is applied to tobacco. It was also domesticated in the east end, where it is called by a word that in a certain district means "to curl" or "fold up." The central district was still free from it as recently as 10 or 12 years ago, but it is slowly and surely gaining on that region, and during the last three or four years cases have been appearing even at Port Moresby. In a few years it will be endemic over the entire coast, a great eastern wave from the Line and Solomon Islands meeting a wave equally great and irresistible coming from the west. There, as in Fiji, the best treatment was found to be fumigation with sulphur, but it is not possible to apply the remedy universally in New Guinea so as to extinguish the disease.

Other Tropical Diseases.

I can only mention by name several other tropical diseases which I have met with that are of special interest and that require investigation. There can be no doubt that ankylostomiasis is indigenous in the Pacific In 1876 it was found in Fijian mountaineers and in recruits from the Solomon Islands Perhaps some of you may be able some day to explain its wide distribution and its exact significance. Cerebro-spinal meningitis was not a native disease but it appeared amongst Indian coolies in Fiji. How it came there was a mystery. Beri-beri was not, I believe, a Fijian malady, but it has been introduced by plantation labourers from Japan. In New Guinea it is indigenous but not common.

In New Guinea there is a curious multiple tumour often met with as large as a walnut. It occurs most frequently about the elbows or the parts of the body that touch the ground when one is asleep on it. This has not been investigated. It is probably parasitic. In the Pacific there is a strange post-mortem appearance that is extremely common and that I trust some of you may throw light on. In the hilum of the kidney there is very often half a teaspoonful of brown or purulent fluid. It is found in the greater number of bodies even if dead only an hour or two. Its cause or origin, so far as I know, has not been made out.

Rabies and "Dingoes."

As an example of the kind of medical legislation as to which you will have to give advice I may first cite from my own experience with rabies. As you all know, there is a species of dog, the so-called "dingo," native to Australia and New Guinea. Where that animal came from is not clear. My distinguished friend Professor Giglioli of Florence gives good reasons for regarding the Australian aborigines as degenerated Aryans. If they are so they probably brought their dogs with them, and this at a time when rabies did not exist in Aryan communities. We shall not consider here whether the barking of dogs is a modern accomplishment or whether the dingo gradually forgot the art The dingo and the dog cross readily and the first cross between them barks. Doubtless, therefore, the dingo would be readily susceptible to rabies. There is a wild dingo on the top of the Owen Stanley range in British New Guinea and a complete specimen was secured and [illegible] in the Queensland Museum, but the result [illegible] is not yet known to me. The domestic dingo is very common in New Guinea as a pet, as a hunter, and as a table delicacy. All the dingoes of a village meet several times a day to howl and they never separate without a fight. They are provided with long, thin, sharp teeth, which they use in season and out of season, but by preference when out of sight. It closely resembles, or is identical with, the Australian dingo. I have never seen a native dingo in the Pacific Islands. The point that most concerns us here is that the Australian and New Guinea dingoes were free from rabies. The Australian colonies have protected themselves from rabies by instituting a term of quarantine on imported dogs. It was seen that rabies introduced into a country like New Guinea with swarms of ill-tempered biting dingoes, among a bare-footed, bare-legged population, and with a wild dingo in the mountains and numberless pigs everywhere, would be a very serious matter not only for that country but also for the whole of Australasia. The matter, therefore, was dealt with on the broadest platform. A representation was made to the great colonies that had charged themselves with part of the burden of maintaining British New Guinea, urging that the Secretary of State for the Colonies should try to induce France, Germany, and Holland to introduce laws similar to those of British New Guinea to prevent the introduction of rabies into their possessions in those seas. The then Prime Minister of Queensland, Sir Samuel Griffith, saw at once the importance of the measure and warmly supported it; it was, I believe, also approved by the Government of New South Wales. The then head of the Government of Victoria thought the proposal more or less ridiculous and was of opinion that France and Germany would give no attention to such a trifle. Lord Knutsford and Lord Salisbury, however, obtained at once the cordial coöperation of the three foreign Governments. There is, therefore, good reason for hoping that now the whole of Australasia is, with reasonable care, secured for all time against the terrible disease of hydrophobia.

The "Jigger."

The question of the introduction of the "jigger" is one that has recently occupied the attention of the Indian Government. To such matters even as the control and distribution of this flea you require to devote time and study. Guided by our experience in Lagos we could only report to the Colonial Secretary that the "jigger" does not cause any noticeable inconvenience on official expeditions, and that it appears in private life to claim very little attention. But a medical officer advising his Government in India would require to know a great deal about the insect before he could venture to recommend any legislative steps regarding it or could suggest that no action whatever should be taken.

Leprosy.

It is probably now generally conceded that the disease of leprosy is communicable and that the isolation of lepers should be carried out in the interests of the community. No aboriginal people whom I have known have ever entertained the slightest doubt as to the contagious nature of the disease. The natives of West Africa isolate the lepers In the South Seas they kept them apart and often buried them alive when they reached an advanced stage of the disease. More than 20 years ago I read in a German author that leprosy was extinguished in Scotland "durch die Entmannung der Männer." I have not been able to find the authority for that statement, the author of which has been dead for many years. Leprosy was at one time apparently not uncommon in Scotland. In the "L'Histoire Universelle" of M. Rambaud it is stated that Scotland's most celebrated king died from this dread disease. The whole subject of leprosy now requires to be studied exhaustively in the light of the new pathology. No doubt some of you are aware that the native Fijian treatment was to bake the sufferer from leprosy near a slow fire It was confidently affirmed that cases were cured in that way. It will be very interesting to see whether a fuller knowledge of the disease will offer any explanation of such a cure.

QUARANTINE.

I would call your attention for a moment to a medico-legal [illegible] to many colonies and to which I [illegible] be given in the courses of [illegible] against the introduction of infectious or contagious disease. In all international conferences on quarantine matters British delegates take their *stand against the imposition of quarantine.* Their system is the isolation of affected or suspected individuals, the disinfection of vessels, and sometimes of cargo. This procedure can be ca [illegible] where there are [illegible] sanitary services. [illegible] where patients and prospective patients can be isolated, it needs a staff of trained and intelligent officers to exercise surveillance over people who may have been exposed to possible contagion, and it requires the means of dealing with any of these wherever he may be found. Here in the United [illegible] sinfecting can be carried out wit [illegible] ompleteness and at small cost. [illegible] the face of the drainage, the ve [illegible] to suspected persons, and the means of dealing with these as well as with infected persons, an outer line of defence may not at any time become necessary. But it is widely different in most colonies. Here the outer line of defence, imposing quarantine on *infected or suspected vessels or persons,* becomes a necessity. You will find that it will tax your powers to the utmost to advise your Governments how best to combine the public safety with the minimum of disturbance to trade, for that in practice is the problem *to solve.* At *Lagos* we have tried to combine the two systems by providing the medical department with the powers necessary to protect us from outside by imposing quarantine on arrivals and to exercise surveillance ashore over persons exposed to a possible infection but who cannot, or need not, be detained in quarantine. Ashore, the medical officers may remove from a community, and isolate, an infected individual; or they may put a house, a village, or a district in quarantine. The small numerical streng [illegible] tion, [illegible] a gre [illegible] that [illegible] line c [illegible] aware [illegible] been [illegible] oth the outer and [illegible] keep out disease. [illegible] pecial and serious study at your hands.

WATER AS A CARRIER OF INFECTION.

Let me impress upon you the extreme desirableness of becoming experts in the examination of water. Nothing is of greater importance in the tropics. Although the new doctrine of malarial fever shows that water is only an indirect agent in the production of that disease it still remains an essential factor in its continuation and spread. It retains all its former importance in respect of other diseases. In West Africa the medical officer should be able to say whether a given well is safe or not on account, for example, of guinea-worm. Water is popularly credited with the origin of the "craw craw" disease in Europeans It doubtless has much to do with the spread of dysentery, typhoid fever where that exists, cholera, and several other maladies. Altogether it is one of those subjects to which you cannot give too much attention. Personally I have always contended that the quality of the water used by a community may have as much, or nearly as much, influence on them as has the quality of the food which they eat or of the air which they breathe. A medical officer is constantly liable to be asked by his Government to report fully on the water-supply of some place or of some community.

CONCLUDING REMARKS.

I cannot conclude these somewhat dry and disjointed remarks without offering my hearty congratulations to you who are to become students at this school. In my opinion your lot is the most enviable of any body of men in this great country. You have already travelled over the ordinary road *of medical education* and have become acquainted with the more frequented parts of the limitless field in which you are to labour. You have become ordinary members of the greatest, the most beneficent, and therefore the noblest of all professions. It can be said with greater truth to day than it could *3000* years ago: Ἰητρος γὰρ ἀνὴρ πολλῶν ἀντάξιος ἄνδρων. Here you are now to be taken into some of the by-paths of medical study. There you will be brought face to face with some of the most interesting problems of science, questions which are of vast importance to the life and health of the individual and which will exert a reflex action that will be felt in many of the transactions of public, of national, and even of international life. I trust and hope that you will leave this school well fitted by your knowledge of your profession to do your part in the exercise of your calling, and that you will have securely planted in your mind that high sense of duty that is the life and soul of religion, of patriotism, and of every efficient public service, and that enables the medical man to devote by instinct, and unselfishly, all his mind and all his strength to the prevention and cure of every disease that affects humanity.

Presidential Address

ON

THE ROMANCE OF SURGERY.

Delivered at the Inaugural Meeting of the 128th Session of the Medical Society of London on Oct. 8th, 1900,

BY JOHN H. MORGAN, M.A. OXON., F.R.C.S. ENG.,

SURGEON TO CHARING CROSS HOSPITAL AND CONSULTING SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

GENTLEMEN,—When it was announced to me that by the kind suffrages of the Fellows of this ancient society I had been elected to the important and honourable position of your president it was not without considerable apprehension that I accepted the position which was offered. For it could not but be felt that to follow in the footsteps of so many distinguished men as have occupied this chair would be a task of no small difficulty. I was, *however, reassured by a knowledge of the* fact that the loyalty of the Fellows of the Medical Society is so thorough and so well proven, that throughout my year of office I could rest secure of the support and assistance of one and all in my efforts to make this society a focus for earnest work amongst all classes of the profession. I have read with interest and profit the addresses which have been delivered from this chair for the last several years, and so many and so instructive are they that to choose a fresh topic was by *no means an easy* matter. Following the example of [illegible] I might have taken you with me on a holiday excursion. [illegible] me in journeys over Europe [illegible] or from Warsaw to Cadiz. Or I might have transported you with me to the barrens of Newfoundland *or the woods* of Nova Scotia, and although I could not have interested you with a disquisition on the flora that we found together I might have treated you to some observations on the fauna of those wild countries, particularly those which lend themselves to pursuit with the rod, the rifle, *or the* gun and have told you many things which are not to be found in works on medicine or surgery as means of diagnosing the age of a hoof-mark or the direction of your camp Indeed, it has often occurred to me that there are the materials for a most instructive lecture on the cultivation *of the powers of* observation which is entailed by many forms of sport and the powers of inductive reasoning thereby engendered. We have only to read Baden Powell's hints on scouting to see how many things we neglect to observe in our daily life, whilst their application has been delightfully *pointed out by a member of our own* profession in the varied experiences of Sherlock Holmes.

But we have returned from our holidays, refreshed and invigorated, as I hope, and ready to apply ourselves to fresh work and possibly to seek new enterprises in the pursuit of our art; and I will ask you to pardon me while I take a brief survey of the present condition of surgery as contrasted with that of a quarter of a century ago and then look forward in the direction of still further progress and advance. For it is little more than five-and-twenty years ago that that great change had been accepted which has altered the whole course of surgical history. Lister had been steadily working to find means to combat those many fell obstacles which obstructed the satisfactory work of the surgeon, and his labours were only just becoming universally recognised and acknowledged. I well remember the first important case in which I endeavoured to apply the principles which Lister was then inculcating in Edinburgh. I was then assistant house surgeon and a case of wound of the knee-joint was admitted under the care of Mr. T. P. Pick. The patient was a young man, aged 19 years, and a circular saw had caused a wound four inches long, dividing the patella longitudinally and incising the outer condyle of the femur to the depth of half an inch and to the extent of three-quarters of an inch. The wound was well syringed out with carbolic acid lotion, the joint also, the wound was closed with sutures of carbolised catgut, covered with protective, dressed with gauze and carbolic oil, and put up on a MacIntyre's splint. Suppuration ensued to a modified extent and the patient recovered, after many months, with an ankylosed knee. This occurred in 1873 and was at the time considered a great triumph, since the recognised course of such cases had previously been amputation and probably pyæmia. Our methods of that date seem crude as compared with those of the present day, when the principles thus followed have been perfected to the system now universally recognised and pursued as the routine method of treatment in such cases. I quote, by way of contrast, the case of a man who was under my care early in the present year who had driven a chisel through his knee-joint into the condyle of his femur. He was treated with what we now recognise as ordinary methods and recovered in a few weeks with complete and perfect movement of his joint.

My hospital duties at that period prevented me from going to study at Edinburgh, but as soon as Lister came to London I was a frequent visitor to his wards. It was my fortune to see the first two cases in which he operated for union of a fractured patella, an operation which has always impressed me as demonstrating more strongly than any other the value of antiseptic methods. As a consequence, out of the last 21 cases of fractured patella that have been admitted to my wards 19 have been successively operated on without a single drawback; the remaining two were not suitable for operation on account of other defects. This alone gives a fair contrast between the surgery of to-day and that of 30 years ago, but the contrast is still more strongly marked when we reflect that there is now no single organ or part of the body which the surgeon is afraid to touch. The brain and spinal cord are freely dealt with for the removal of tumours or other sources of interference with their functions. The lungs are opened for the removal of tumours and for the evacuation of pus that lies in their centre and even the pericardium is tapped and drained and the heart itself is sutured.

In the abdomen there is no single viscus or part which is free from the attacks of the surgeon; even the liver, which has long been regarded with awe, has been dealt with for the removal of tumours and has been sutured in order to render it less mobile. As to the amount of intestine which can be removed without any obvious detriment, it would appear to be no longer a matter of inches, but even of feet or possibly yards, whilst from a few recently recorded operations it seems possible that the stomach itself can be altogether dispensed with. I shall not, however, detain you with recalling facts with which you are all familiar, the more so since they have been put before us in a most eloquent and comprehensive form by Mr. Pearce Gould in the address which he delivered before the society in 1895. In that oration he pointed out the changes that had taken place in operative surgery during the past 30 years and the vastly extended area which had been opened to the surgeon, and he paid a justly merited tribute to him to whose patient labours this evolution in surgery is mainly due, Joseph Lister, who has made this society the medium for many of his most important communications, and who only within the past week in the Huxley address, delivered at the school to which I am attached, has shown that age does not wither or time change the depth of his insight into the problems that first occupied his thoughts 30 or 40 years ago, or have they dimmed one whit his deep interest in the further development of the art which he has done so much to glorify. How many of us can remember, like our orator of this year, to have seen maggots in the pus that surrounded a compound fracture? and when we contrast the experience of our student days with our practice in the present, are we not justified in saying that we have witnessed and partaken in the romance of surgery?

But just as romance belongs as much to the past as to the future, so we must not be content to rest upon our oars and fancy that we have reached finality. Indeed, the more one reflects, the more one sees how much there is still left for us to aim at, and it is in the hope that I may indicate some of the paths which we must seek to follow that I base the remainder of the remarks which I have to address to you. If we come to analyse this recent progress of surgery I think that it will be acknowledged that the advance has been much more marked in the direction of technique and that the progress of diagnosis has hardly advanced at an equal pace, and that it is in this direction that we must more specially direct our efforts. So great, indeed, is the confidence in the value of operation that it is no infrequent experience to find cases sent to the hospital with the simple indication "for operation" or "for abdominal section." But as in war the prudence and wisdom of a general are as often shown in declining as in seeking an engagement; so the skill of a surgeon is as frequently exhibited by refusing as by consenting to operate. It may be truly said that by the impunity with which we open the abdomen we have learnt much to account for symptoms which were otherwise inexplicable; but just as Hunter regarded an amputation as a confession of failure, so I look forward to the day when exploratory operation will rarely be advised and when diagnosis will be formed by a careful consideration of symptoms, and reliance placed on that tactile sense which, as Mr. Treves has pointed out, runs risk of being left uncultivated by the modern surgeon. It may, nay, it must, occasionally happen that when all points have been carefully considered there is no other course to follow. It lately occurred to me to be asked by my colleague to see with him a woman who gave no sign of any neurotic tendency. She had for a considerable time been under the care of Dr. J. Mitchell Bruce, a warrant that every point which could lead to a diagnosis had been most carefully considered. She was 32 years of age and of fairly healthy appearance. The hair was prematurely grey. She had enjoyed fairly good health till October, 1898, but from that time till the corresponding month in 1899 she was troubled with persistent vomiting, occasional slight hæmatemesis, and tenderness in the epigastrium. She was given every possible treatment—diet, change of air, &c.—but the vomiting persisted and the woman became more and more thin and emaciated. Naturally, the conclusion was forced upon us that some ulceration existed. I opened the abdomen and searched all the organs. The stomach and pylorus, the posterior surface of the stomach, the kidneys, the liver and gall-bladder, and the cæcum all appeared normal and healthy. There were no adhesions anywhere. The wound was closed and except for two slight attacks of vomiting she never had a bad symptom, and she wrote in July last, to say that she was working on a farm, had had no more gastric symptoms, and was getting fat. Here without ocular demonstration it was impossible to assert that no lesion existed, but why the symptoms abated must still remain a mystery.

How largely we have profited in the direction of diagnosis by the experience gained from operative measures cannot be better illustrated than by the case of the gall-bladder. Courvoisier has laid it down that when the gall-bladder is distended and there is coincident jaundice gall-stones are not the cause but more probably cancer of the pancreas, growths in the common bile-duct, or external compression of that duct. The gall-bladder does not become distended, though it may possibly just be felt, or stones in it may be perceived when a calculus is blocking the common duct and giving rise to jaundice, because the previous presence of calculi leads to thickening of the peritoneal covering of the gall-bladder which resists pressure and therefore prevents distension; also because the passage of the calculus along the cystic duct excites inflammation in and around the walls of the duct, which is followed by cicatricial changes that resist pressure and prevent distension. On the other hand, a single calculus impacted in the neck of the gall bladder or in the cystic duct may be followed by great distension, due to secretion from the lining membrane, but, under these circumstances, jaundice is absent. Exploratory operations in the subjects of cancer hasten the end and bring reproach upon surgery. If the gall-bladder is incised hæmorrhage may occur and a continuous oozing may follow, and operation for the relief of distension of the gall-bladder by continuous drainage in cases of cancer of the head of the pancreas with jaundice are not advisable. These conclusions have been arrived at through the extensive operative experience of Mr. Mayo Robson. Dr. Osler, again, points out the importance of recurrent rigors in cases where no suppurative foci exist. Thus the practical experience of the surgeon and the careful consideration of facts by the physician combine to formulate a series of data by which the phenomena of disease may be recognised and by which the necessity for exploratory operations is gradually diminishing.

The call for early recognition is nowhere more urgent than in the case of malignant tumours of whatever nature or in whatever tissue, a fact which is forcibly pointed out in the most recent edition of Mr. Butlin's interesting work on the Surgery of Malignant Disease. Are we right in trusting to the knife as our only means of eradicating this fell scourge? May it not be hoped that in some way electricity may destroy the elements of tumour growth or that some form of antitoxin may be found which will counteract the parasite that gives rise to the tumour?

Looking to other fields of surgery we may note that tumours, both innocent and malignant, have been removed from the liver, and Dr. Keen of Philadelphia gives a table of 76 cases in which operation has been performed, whilst the interesting lectures of Mr. Mayo Robson record the vast field of successful surgery which has been afforded by the gall-bladder and its ducts. As to the methods and appliances which have been adopted for removing portions of intestine they can be counted by the hundred and it is in itself a study for the surgeon to keep abreast with them and to estimate their respective values. So, too, it is with all the other parts of the abdomen that increased experience induces novel methods, many of them improvements and advances on what had gone before. The operative surgery of the stomach presents in a remarkable way the great progress which has been made in this direction. In 1880 Mikulicz first sutured the stomach for a perforation. In July, 1900, Dr. Finney of Baltimore collected 268 cases amongst which were 139 recoveries and 129 deaths (a mortality of 48 per cent.). Subphrenic abscess occurred in 20 per cent. and the cause of death in the majority was sepsis. But the point of importance in this particular direction is the difference of mortality depending upon the period at which operation was performed. This has been strikingly demonstrated by Mr. L. A. Bidwell in a paper published in the *American Journal of the Medical Sciences*, in which he shows that the earlier the operation in cases of perforation the greater the chances of success; whilst Tinker of Baltimore estimates the recoveries in cases submitted to early operation at 83 78 per cent Mr. Mayo Robson collected 188 cases of gastric ulcer, treated surgically, of which 157 recovered and 31 died, thus giving a mortality of 16 4 per cent., and also pleads in favour of more early surgical treatment in cases of an intractable character. Indeed, the stomach would appear to have been of recent years the most prolific area for surgery Not only are wonderful operations performed but marvellous names are invented. Gastrectasia or dilatation of the stomach is treated by gastroplication or gastro-enterostomy. Gastroptosis or moving downwards of the stomach, as evidenced by a change in position of the lesser curvature, has been dealt with by Mr. Treves who in the case of a young woman, aged 22 years, found the omentum adherent to a mass of tuberculous glands in the mesentery, preventing him from raising the stomach. He removed the glands and then could restore the stomach and liver, both of which were markedly displaced, and secured the liver with three stout silk ligatures. An American writer on this subject concludes in these words: "To resume the facts brought out by these operations for gastroptosis it is evident that improvement is not difficult to bring about, whether one secures the liver only, sutures the stomach itself or the mesocolon to the abdominal wall, or shortens the gastro-hepatic omentum, or finally removes a segment of the abdominal wall. The condition is usually a complex one and probably a simple gastrorrhaphy will not be sufficient, but should be assisted by right nephrorrhaphy or hepatorrhaphy." What would our ancestors have said to this? But then, the Americans are a go-ahead people.

The surgery of the brain has advanced greatly since Horsley, in 1886, published his directions for operating, and Ferrier and Hughlings Jackson showed how to locate pressure. By this means abscess, whether following otitis media or due to other causes, can be successfully located and satisfactorily drained; indeed, this is an almost daily performance and Mr. Ballance regards a small opening in the cranium as responsible for some of the failures. As to brain tumours Mr. Butlin in his recent edition says: "It is interesting to observe that surgeons of large experience in brain-surgery of all kinds—for example, von Bergmann—appear to grow less hopeful of the future of the surgery of tumours of the brain"; but Mr. Ballance writes to me that one great success seems to justify perseverance. Tuberculous brain tumour is, in his opinion, a contra-indication to operation, "but encapsuled brain tumours give the best results and they seem most frequent beneath the tentorium. The infiltration varieties cannot be wholly removed, but the operation relieves headache, vomiting, and blindness from optic neuritis." The successes of spinal surgery are more numerous. Caries and tumour here seem to offer a fair return to the surgeon for his operative efforts.

In another direction I think that we may look for a further development of the procedure which has been carried out with such success by Mr. Ballance in the treatment of chronic purulent otorrhœa by the epithelial grafting of the raw bone cavity. I see no reason why a similar procedure should not be followed in cases of extensive necrosis of other bones, or even in some cases of joint disease, as supplementary to the ordinary operation of erasion. In the case of another intractable defect which has hitherto baffled all efforts of surgeons to deal satisfactorily with it some such treatment might be carried out, and for the remedy of ectopia vesicæ the suggestion has recently been made to transplant a portion of the bladder of a sheep to the lower lateral abdominal fasciæ of the patient After a period of seven or eight days, as proved by experiments on animals, the union of the two tissues is sufficiently strong to allow a plastic operation whereby a skin flap, with the bladder attached, may be swung over upon the extruded bladder and the edges of the attached piece of bladder sutured to the defective parts.

The experience of modern warfare renders it probable that bullets may require to be removed from the substance or even the cavity of the heart. The occasions may be rare, but they must none the less be met by prompt and adequate measures. Not that the surgery of the heart is a new subject, for so long ago as 1648 Rivolan suggested trephining the sternum in cases of pericardial effusion, and a summary of 80 cases of paracentesis for serous and purulent effusion has been published by Dr. Samuel West, and Jamain collected 121 cases of wound of the heart in which there were 16 recoveries. Stabbing wounds are less dangerous than bullet or cutting wounds John Bell is said by Foy of Dublin to have been the first to remove a foreign body from the pericardium and to cleanse and to drain it. In 1898 Podrey did a pericardotomy for a bullet wound of the heart, the pericardium was evacuated, washed out with boric acid lotion, and a fibrino purulent deposit was stripped from the heart. A wound one centimetre long was found in the right ventricle. A needle was introduced to feel for the ball and passed right through the heart, which was palpated and the ball felt for but not found. The wound of the heart was not sutured. The patient recovered, and several cases are on record in which wounds have been successfully sutured, one notably by Pagenstecher of a wound of the left ventricle three and a half centimetres long which was treated by four sutures and the patient recovered

The best means of treatment of chronic enlargement of the prostate, whether by suprapubic, perineal, or urethral prostatectomy, or by orchidectomy, or by vasotomy, or vasectomy, is a subject that I should much like to hear discussed at this society

The further development and application of the x rays to surgery and medicine is a study which I should like to see appropriated by members of the profession. I believe that it is still in its infancy and that there is a great future before it. But in order that we may obtain the full advantages of its resources it appears to me that the study must be pursued by men having a thorough medical training and must not be allowed by them to fall into the hands of mechanicians lest its progress as a scientific aid to diagnosis be checked I heartily commend it as a new form of specialty to those who have time and opportunity to pursue this entrancing study.

It will be objected that no man can be expected to have the whole gamut of surgery in his mind, or rather at his fingers' ends, and that thus the tendency to specialism, which is daily becoming more and more marked, must continue to increase till—like the ancient Egyptians, as Sir William MacCormac reminds us—there are as many branches of medicine as there are organs of the human body. Whether this is to be brought about, as Mr. Butlin has suggested in his Cavendish Lecture, by a community of workers, "a direct and organised scheme for research and the application of pathology to our art," or by the patient labour of individuals remains a question for the future.

If there ever was a subject on which surgeons once deluded themselves into the happy fancy that they had reached a climax of success it was the treatment of simple fractures. But the spell is broken, the veil of self-satisfaction is lifted, and we are told that our lines are false, our measurements are incorrect, and that our methods tend only to incorrect axes and, consequently, to the starting of joint lesions and the confirmation of defects, for which our treatment is alone responsible. Such allegations are somewhat startling, and one wonders if the bones of Hamilton, of Pott, and of Astley Cooper lie quiet in their graves, or if their ghosts are wandering uneasily in Cavendish-square. But in face of this accusation it behoves us to look into the matter and to consider how far and in what cases should the fragments of a fractured bone be brought into apposition by wire and screws; and whether the disturbance of the tissues, which is involved in their application may not often cause more harm than if the fracture were treated by more ancient methods?

In the foregoing remarks I hope that I shall be pardoned for confining myself to that branch of work to which my past years have been devoted. But I am well aware that, although not so strikingly evident, the advance of medicine has been steady and constant. It is in the nature of things that disease once asserted may be beyond reach of cure. But the art of the physician in the prevention of disease, in its early detection, and in guiding it to a successful issue has progressed with strides almost equal to those of which the surgeon so justly boasts, and the two branches of our art are every day more closely united by the fact that the physician by his early diagnosis appreciates the moment when he may seek the assistance of a surgical ally, and the two are brought together in the combat against many ills which neither alone might have sufficiently appreciated, and in their union is a strength which every year makes more victorious. May this combination grow ever stronger and may their united efforts ever tend to ease the sufferer and to relieve the afflicted! For such is the end and object of our art.

NOTES ON THIRTY-ONE CASES OF DIPHTHERIA TREATED WITH ANTITOXIN.[1]

BY JOHN MACKENZIE, L.R.C.P., L.R.C.S. EDIN., L.M., L.F.P.S. GLASG.

To describe in detail each of the 31 cases of diphtheria of which I have made notes in this paper would make it too long, hence, for the sake of brevity, I have grouped them according to their clinical features and anatomical relations. They extend over a period of five years and consist of the most serious cases which occurred in my practice. With the exception of three cases of acute laryngitis simulating croup in which serum was used as a test they all presented so typical and characteristic an appearance as to render a clinical diagnosis of diphtheria almost a certainty. There are practitioners who view with considerable misgiving a diagnosis of diphtheria unconfirmed by a bacteriologist. The clinical diagnosis, they aver, "is so liable to err, for a dirty, greyish membrane is produced by other causes than Klebs-Löffler bacillus, by streptococci, by caustics, and it not infrequently follows excision of the tonsils if the throat is not kept very clean. An exudation *per se* proves nothing; the specific organism must be discovered."

It cannot be disputed that many cases of sore-throat with an exudation are now recognised to be benign and non-diphtheritic, just as we know that cases of sore-throat free from exudation contain the Klebs-Löffler bacilli; even then the path of the bacteriologist is not without its difficulties and dangers. Should erroneous conclusions be accepted and acted on, what then? Your precious time is lost and a serious mistake is committed; nor is it altogether becoming of the physician to defer absolutely to the bacteriologist. Does not the bedside present a field of observation and reflection with objects of interest equal to the laboratory? One cannot help thinking after reading their works that our great physicians have as deep—perhaps deeper—an insight into nature's ways as our great bacteriologists. Is not what we term "disease" nature's physiological laws organised on a different plane? However, it is not meant to discuss in this paper the bacteriology of diphtheria.

GROUP I.—THREE CASES OF LARYNGEAL DIPHTHERIA (I.E., THE LESION BEGAN IN THE LARYNX AND ULTIMATELY EXTENDED TO THE PHARYNX).

CASE 1.—A female infant, aged three years, had been ill several days before I saw her on March 30th, 1895. The temperature then was 102° F. and the pulse was 130. The child had a hoarse, rough cough, prolonged inspiration, and much laryngeal stenosis, and her aspect betrayed great anxiety. She was restless and irritable with occasional fits of dyspnœa. An examination of the throat revealed nothing beyond acutely congested pharynx and tonsils, but the symptoms of a typical fatal croup were unmistakeable. Emetics, poulticing, medicated vapours, and swabbing the throat with antiseptics were vigorously prosecuted but with no relief. Antitoxin was then in its infancy and few believed in it. Early on the next morning I telegraphed to Messrs. Burroughs and Wellcome for two doses of 1500 units each of anti-diphtheritic serum which arrived at 6 P.M. the same day. When I went to inject it at 7 P.M. the little sufferer was livid, her voice was reduced to a whisper, and her condition was distressing beyond description. I told the parents that [illegible] the child would die from asphyxia in the [illegible] That a fatal issue was fast approaching I had no doubt whatever; but the reason for my giving so gloomy a prognosis was that the parents on seeing my syringe and needles demurred to the injection. They were willing for me to give the antitoxin by the mouth but not by injection. However, after much parleying I carried my point and gave an [illegible] anti-diphtheritic serum between [illegible] morning her general condition [illegible] temperature, which was at the [illegible] was now down to 100°. The c[illegible] the dyspnœa was much less. At the middle of the third day of my attendance the patient had a serious attack of dyspnœa followed by collapse which greatly alarmed the parents. It was then proposed to give a second injection but this they refused point-blank on the plea that there was no use in inflicting more punishment on her as she was sure to die. By this time small patches of white or greyish-white membrane were developing on the tonsils and the margin of the soft palate. In an hour or so she rallied and was removed to the Nottingham General Hospital where tracheotomy was performed soon after admission, but, according to my information, no serum was injected. She made an excellent recovery.

CASE 2.—A female infant, aged three years, when first seen by me on June 5th, 1899, had a hoarse, rough, croupy cough, which was said to have been very troublesome for the last three or four days. The temperature was 100° F., the pulse was 130, and the respirations were 30. Laryngeal stenosis and dyspnœa were at times extreme. At 3 P.M. on the same day 1500 units of Messrs. Burroughs and Wellcome's anti-diphtheritic serum, which I had had in my house for over a month, were injected between the scapulæ. On the next morning small white patches were observed on the tonsils and the patient's condition was distinctly worse. The dyspnœa was particularly distressing, the chest heaving and the epigastrium retracted at every inspiration. The little sufferer was continually thrusting her hands down her throat, with gazing eyes now fixed on one and then on another as if imploring for help. The dyspnœa, which had been extreme before, was now no longer paroxysmal but continuous. Such a scene is painful to all, especially to the physician who is called in to render aid to a sufferer of tender years whose helplessness deeply appeals to his feelings. Callous, indeed, must be the nature which could ever forget such a sight, and equally ungrateful must be the man who will ever cease to be thankful that science—*pace* the anti-vivisectionist—has placed within his reach so [illegible] antitoxin for relieving such agony. [illegible] for another dose of serum which [illegible] the second day. The child was then *in extremis*. The injection was this time given in the subcutaneous tissue of the abdominal wall. When the patient was seen three hours afterwards the condition was improved. The cyanosis was gone, the dyspnœa was less, and the cough was much softer. Next morning the child was playing with her toys. The white patches on the tonsils and the fauces made no advance and completely disappeared in 24 hours, as also did the stenosis. This was by far the most [illegible] ver knew to recover.

---

[1] A paper read before the Nottingham Medico-Chirurgical Society on March 7th, 1900.

[illegible] on July 17th, 1899. A female [illegible] been ill for several days previously to being seen. Her cough was then hoarse, rough, and croupy, but the dyspnœa and laryngeal stenosis were not very pronounced. An examination of the throat revealed two or three small white patches on the tonsil which could not possibly be continuous with the laryngeal membrane. At 9 P.M. when the injection was given, similar patches were observed on the opposite tonsil. The temperature was then 105° F. and the pulse was 140. Respiration was irregular and inspiration was prolonged. The urine was highly albuminous. 1500 units of anti-diphtheritic serum were injected into the subcutaneous tissue of the abdominal wall. Next morning the general condition of the patient was much improved. On the 19th, the third day, the progress had continued. The membrane had completely disappeared from the tonsils and respiration was free, indeed almost normal. The child made an excellent recovery.

Group II.—Six Cases of Pharyngeal Diphtheria gradually extending to the Larynx.

Case 4 (May 15th, 1895) was that of a female child, aged seven years; Case 5 (August 3rd, 1896) was that of a male child, aged four years; Case 6 (August 8th, 1896) was that of a male child, aged six years; Case 7 (Sept. 27th, 1896) was that of a female child, aged five years; Case 8 (Dec. 11th, 1897) was that of a man, aged 30 years; and Case 9 (July 13th, 1899) was that of a male infant, aged 17 months.

Clinically this group is a good example of the type of diphtheria beginning with a d[illegible] the lateral sides of the phar[illegible] soft palate, and the posterior [illegible] not checked, gradually inv[illegible] The symptoms are essentially asthenia, moderate temperature (from 99° to 100° F.), quick pulse, much constitutional depression, and albuminous urine. I noticed that if the membrane was yellowish or greyish yellow, indicating age, it disappeared under the influence of antitoxin by sloughing, leaving necrosed tissue under. If, on the other hand, it was recent, and whitish grey in colour, it simply melted away. No separation was seen at the periphery but a gradual thinning in all its parts, and when the exudation had cleared away the mucous membrane, though acutely inflamed, presented no raw granulating surface filling up necrosed hollows. Cases 4, 5, 6, and 7 showed marked improvement next morning after the injection and made good recoveries. Case 8, which was that of a publican, is placed in this group because the condition of his throat was anatomically and clinically identical with that of the others, but more especially as the case so forcibly illustrates the evils of delay. The onset of diphtheria to the professional mind is sufficiently insidious; to the laity it is synonymous with laryngeal stenosis and dyspnœa. Medical aid is never sought till these symptoms alarm the friends, which often means in a case of pharyngeal origin a week or two of illness. The patient died suddenly from syncope two hours after I saw him and four hours before serum could be obtained. In Case 9 the patient had been suffering from measles complicated with broncho pneumonia for two weeks before any throat mischief set in. The onset of diphtheria was early noticed and serum was used with little or no delay. The membrane which covered the tonsils and pillars of the fauces and to a lesser extent the epiglottis perceptibly diminished, but the little sufferer succumbed to his pneumonic lesion.

Group III.—Three Cases of Laryngeal Diphtheria confined to the Larynx and Glottis and difficult to Diagnose from Membranous Croup and Acute Catarrhal Laryngitis.

Case 10 (May 6th, 1895) was that of a male child, aged two years; Case 11 (Sept. 27th, 1895) was that of a female child, aged six years; and Case 12 (July 11th, 1899) was that of a female infant, aged five months.

This group presented very much the same symptoms as the others—a febrile condition, a temperature ranging from 100° to 102° F., a hoarse, rough, croupy cough, much laryngeal stenosis, dyspnœa, and enlargement of the glands of the neck. In one case (Case 12) the swelling extended to the parotids. 1500 units of antitoxin were given on the evening of the first day. The improvement on the next morning was pronounced in Case 10 and Case 11. The harsh rough cough was moist and soft and the anxious look and laboured respiration gave place to easy breathing and cheerful, happy expression. In Case 12 (the infant) the condition was worse. The stenosis and dyspnœa were very distressing, the glandular enlargement was increased, the tonsils were very much swollen, and there was dysphagia with paralysis of the soft palate. A second injection was given eight hours after the first but there was still no improvement and the patient died 24 hours after the second injection. This was the youngest patient I ever saw suffering from diphtheria, for young infants have a natural immunity against certain infectious diseases—e g., scarlet fever and diphtheria. I have often observed in the course of my work as public vaccinator that insusceptibility to the action of lymph is much more common amongst young infants from one to two months old than children aged four months and upwards. May not the young infant, even if it be five months old, present analogous insusceptibility to the action of serum? Certainly in this case, though used very early in the complaint, it entirely failed.

Group IV.—Nine Cases of Pharyngeal Diphtheria confined to the Pharynx, Soft Palate, and Posterior Nares.

Case 13 (August 19th, 1895) was that of a male child, aged five years; Case 14 (Sept. 26th, 1896) was that of a female child, aged six years; Case 15 (Nov. 9th, 1896) was that of a male child, aged five years; Case 16 (Oct. 29th, 1898) was that of a man, aged 30 years; Case 17 (Jan. 28th, 1899) was that of a male child, aged five years; Case 18 (May 6th, 1899) was that of a male child, aged four years; Case 19 (May 11th, 1899) was that of a girl, aged 15 years; Case 20 (May 16th, 1899) was that of a woman, aged 30 years; and Case 21 (Feb. 24th, 1900) was that of a female child, aged five years.

The nine patients in this group were fully a week ill before I saw them. One in particular, who was excessively ill, was notified as suffering from diphtheria on Oct 29th and had the first injection of serum on Nov. 5th, seven days after notification. The cases were of a low depressing type with a filthy yellowish membrane covering the sides of the pharynx, the tonsils, the uvula, the fauces, and the posterior nares. The temperature was never above 100° F., the pulse was of low tension (from 110 to 130), the tongue was coated and dry, the appetite was lost, and the patients were pale and [illegible] cases the exhaustion was so great that [illegible] to be removed [illegible] them. [illegible] given on the first day of seeing them, aided by antiseptic washing of their throats and stimulating diet. In every case the first injection produced marked improvement within a few hours. As the cases were of long standing it was considered advisable to repeat the injection next morning. They made excellent recoveries.

Group V.—Six Cases of Post-scarlatinal Diphtheria (Clinical Distinctions from Ordinary Diphtheria).

Case 22 (Nov. 9th, 1898) was that of a female child, aged five years; Case 23 (Nov. 10th, 1898) was that of a male child, aged seven years; Case 24 (Nov. 18th, 1898) was that of a female child, aged seven years; Case 25 (Nov. 22nd, 1898) was that of a male child, aged eight years; Case 26 (Jan. 28th, 1899) was that of a male child, aged three years; and Case 27 (July 15th, 1899) was that of a man, aged 30 years.

In post-scarlatinal cases the exudation generally begins about the middle of the second week of illness and is very extensive, covering the sides and posterior wall of the pharynx, the tonsils, the uvula, the palate, and the nasal passages. The involvement of the nasal passages is more common in post scarlatinal diphtheria than in ordinary cases. The same remark, I think, also applies to the Eustachian tube of a voluminous fibroid, in three cases for fibroid with salpingitis, in two cases for cancer, in one case for fibroid with dermoid cyst, in one for fibroid and ovarian tumour, in one for a dermoid cyst with salpingitis, and in one case for fibrous tumour of the uterus in which ovariotomy had been previously performed for a suppurating ovarian cyst.

Dr. Doyen's technique of abdominal hysterectomy is so simple and so largely responsible for the almost startlingly small mortality (from 2 to 4 per cent.) that it is strange that it has not yet been generally adopted in English practice, with or without its latest modifications as shown at the International Congress of Gynæcology at Amsterdam in August, 1899. The English surgeons and gynæcologists whom I have seen operate or who have discussed the matter do not appear generally to have adopted any one technique—some preferring what is known as the American method, or some personal modification of it, while a few appear still to use the serre-nœud. Physicians and surgeons, however, all the world over are agreed in one thing—viz., the desire to find out what is best for their patients—that is, in this matter the operation that is at once the simplest and that gives the best results. Uterine disease of one form and another is so frequent that if we include affections of the annexa it is undoubtedly the most common condition that forces us to open the abdomen. The general adoption, therefore, of the excellent technique that Dr. Doyen has devised, and which is largely practised on the continent, cannot fail to be of benefit. It has the two great advantages of being certainly the simplest method of removing the uterus, whether in a simple or a complicated case, and therefore of being capable of completion, even by a surgeon unfamiliar with it, in half an hour or less.

Perhaps the chief value of the operation to many minds will lie in the fact that injury to the ureter or bladder is practically impossible (I have not seen either wounded in from 30 to 40 cases), and the peritoneum being completely closed the risk of infection is reduced to a minimum.

CASE 1.—Laparotomy for uterine fibroid with double salpingitis was performed on a patient, aged 49 years, on March 29th, 1899. The fibroid was of about the size of a fœtal head, and the salpingitis on the left side was of considerable volume. The patient, who had come from Alexandria, Egypt, for the operation, remained 26 days in the clinique and made an excellent recovery.

CASE 2.—Abdominal hysterectomy for fibroid was performed on a patient, aged 38 years, in April, 1899. The fibroid was of the size of an adult head. The only complication was due to abundant vascular adhesions of the omentum to the tumour and an uneventful recovery was made.

CASE 3.—Abdominal hysterectomy for fibroid was performed on a patient, aged 35 years, on April 25th, 1899. The cervix was displaced high up by the tumour which occupied chiefly the left cul-de-sac. Its removal was easy though the broad ligaments were short and were both clamped and cut in order to facilitate the elevation of the tumour and uterus and the opening of the posterior vaginal cul-de-sac. The patient remained 22 days in the clinique, leaving well.

CASE 4.—Abdominal hysterectomy for large fibroid was performed on May 9th, 1899. The case was uncomplicated except that the closure of the peritoneum by suture over the vaginal opening caused some difficulty.

CASE 5.—This case was one of simple uncomplicated abdominal hysterectomy for large fibroid and was performed on a patient, aged 47 years, on May 16th, 1899.

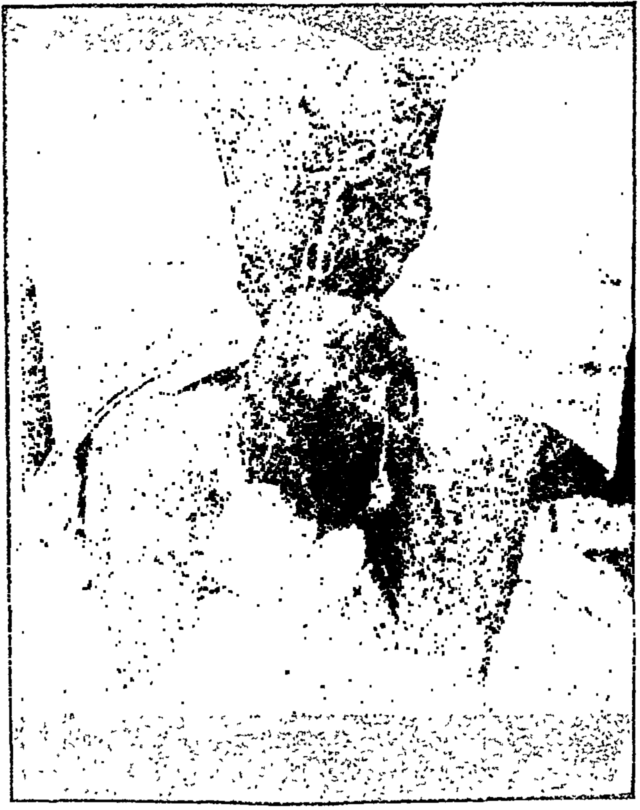
CASE 6.—Abdominal hysterectomy for fibroid filling the posterior cul-de-sac was performed on a patient, aged 33 years, on May 30th, 1899. This case presented difficulties owing to intestinal adhesions which gave trouble and had to be very carefully separated. The peritoneum was closed, but a drain was introduced sub-peritoneally from Douglas's pouch into the vagina. The patient made a good recovery and left the clinique on the thirty-eighth day.

CASE 7.—This case, in which an operation was performed on a patient, aged 44 years, on June 6th, 1899 is quoted because before the close of the operation it was found necessary to remove the uterus though at first only ovariotomy was contemplated. The case was one of a large cyst of the right ovary containing about 10 litres of fluid and extending between the layers of the broad ligament. The adhesions were dense and the shell of the tumour was separated with great difficulty. The left annexa were also removed as well as the uterus, which was large and fibromatous. The patient left well on the twenty-fifth day.

CASE 8.—This was a case of uncomplicated abdominal hysterectomy for fibroid and was performed on a patient, aged 43 years, on June 9th, 1899. The patient left the clinique well in 24 days.

CASE 9.—Abdominal hysterectomy for large fibromatous uterus was performed on a patient, aged 47 years, on June 19th, 1899. There was a cancerous degeneration of the cervix invading the left vaginal cul-de-sac. This degeneration involved the left ureter, which was removed for about three centimetres, the lower end being then sutured into the bladder, and a ureteral catheter was passed into it *viâ* the urethra through the bladder. In spite of the serious nature of this case recovery was practically uninterrupted. The catheters were removed on the eighth day and the patient left the clinique on the twenty-fourth day. When heard from at the end of September, 1900, she was in excellent health.

FIG. 1.



Illustrating the first step, the abdomen opened, and the tumour drawn out above the pubes. Behind are seen the handles of the forceps placed in the vagina. (Plate XIII., No. 1, facing p. 458, Macnaughton Jones, from photograph lent by Doyen.)

CASE 10.—This was a case of abdominal hysterectomy for large fibroid, the patient being aged 48 years. A rare and interesting feature in this case was that anteriorly to, and quite apart from, the uterus was a large dermoid cyst apparently between the layers of the great omentum. Both were enucleated without difficulty. The posterior peritoneal cul-de-sac was drained per vaginam. The patient left the clinique well in 24 days.

CASE 11.—Abdominal hysterectomy for fibroid with double hæmatosalpinx was performed on a patient, aged 42 years, on Sept. 5th, 1899. The operation was uncomplicated and the patient left the clinique well in 25 days.

CASE 12.—Abdominal hysterectomy on account of pain and fibrous tumour to the left of the uterus was performed on a patient, aged 35 years, on Sept. 29th, 1899. In this case there was also old inflammatory peritoneal thickening. The patient left well on the seventeenth day. Laparotomy had also been performed by Doyen upon this patient seven months before (on Feb. 23rd, 1899) for a suppurating cyst of the ovary. The patient arrived at the clinique in almost a dying condition, as the cyst had ruptured and there were both pelvic and general peritonitis. Both annexa were removed, but the uterus was left to aid the peritoneal suture. A drain was placed in Douglas's pouch and led into the vagina. The patient made a surprisingly good recovery and left the clinique on the nineteenth day.

CASE 13.—This was an abdominal hysterectomy for suppurating dermoid cyst with double salpingitis and was performed in October, 1899, the patient being 50 years of age. The case was rendered difficult on account of the close adhesions that had formed between the peritoneum of the small pelvis and the tumours and the intestine. A good recovery was made and the patient left the clinique on the twenty-sixth day.

CASE 14.—Abdominal hysterectomy for large fibroid was performed in October, 1899, on a patient, aged 38 years. There were a slight amount of albuminuria and persistent diarrhœa, so that for several days after the operation the patient's condition seemed precarious. The patient left the clinique well in six weeks, her departure being delayed by tardy healing of the silk suture.

CASE 15.—This was a case of hysterectomy for voluminous fibroid and was performed on Oct. 19th, 1899, the patient being 55 years of age. Some difficulty was experienced in getting the cervix raised, but otherwise the operation was uncomplicated and the patient left the clinique well on the twenty-second day.

CASE 16.—Hysterectomy for cancer of the uterus was performed on Oct. 11th, 1899, the patient being 55 years of age. She recovered well from the operation and left the clinique in 22 days.

CASE 17.—Abdominal hysterectomy for fibroid and salpingitis was performed on Dec. 5th, 1899. The patient, who was 28 years of age, made an uneventful and good recovery.

CASE 18.—The patient was 47 years of age and abdominal hysterectomy for large fibroid was performed on Dec. 8th, 1899. The incision was of unusual length on account of the size of the tumour and extended from the pubes to about midway between the umbilicus and ensiform process. Both the operation and the recovery were uneventful.

TECHNIQUE OF DR. DOYEN'S TOTAL ABDOMINAL HYSTERECTOMY FOR FIBROID.

It is curious to note how few surgical ailments there are in the treatment of which, no matter how frequently they may occur in practice, surgeons generally are [illegible] be adopted. In [illegible] nce, surgeons dif[illegible] of a century ag[illegible] methods of operating equally approach the ideal of excellence. The fault seems to lie in an excessive conservatism and in the lack of sequence and logical coherence in the literature of the arts of medicine and of surgery—a fault that is continually made evident by the re-discovery and the re-publication of suggestions and of facts that were know[illegible] have been forgotten by man[illegible] there are exceptions to this [illegible]rgeon will describe the technique of an operation so simple, so clear, and so perfect that it takes its place at once never to be forgotten. Thus, Macewen's method of osteotomy for genu valgum is probably practised by surgeons in every civilised country in the world and there is none to dispute its place. Who, however, would dare to name the best operation for the radical cure of hernia, for a cerebral or cerebellar abscess, for an intestinal anastomosis, or for a gastro enterostomy? The names of the claimants are legion.

I submit that Dr. Doyen's technique of the enucleation of uterine fibroids by abdominal hysterectomy is as perfect as operative technique can be. Dr Doyen has made several minor modifications since he first described it at the International Congress of Gynæcology at Brussels in 1892, but its three chief advantages remain These are—(1) the retention of sufficient peritoneum around the opened vagina to admit of complete closure of the peritoneal cavity; (2) the avoidance of the use of clamps, ligatures, and forceps prior to the section of the broad ligaments; and (3) the applicability of the operation to the enucleation of all forms of uterine and broad ligament fibroids. I will now give a brief *résumé* of the technique and then describe each step in detail.

The patient is placed in Trendelenburg's position. The posterior vaginal cul-de-sac is opened from the abdomen by scissors cutting upon curved forceps introduced per vaginam by the assistant. The cervix is then easily caught by its posterior lip and freed by cuts of the scissors to right and left until completely circumcised. It is then drawn well up, *separating itself* from the bladder. The right broad ligament is isolated and cut and then the left. The success and safety of the operation lie in its simplicity and rapidity, the complete closure of the peritoneal cavity, and the extra-peritoneal treatment of the pedicles of the removed annexa.

FIG. 2.

Illustrating the removal of the uterus and hæmostasis of its pelvic attachments (Plate XIII., No 2.) The cervix is seen caught by the tenaculum after incision behind the posterior lip of the cervix upon the point of the forceps in the [illegible]n The right [illegible] ceps need be applied ;

First step: abdomen opened, and tumour drawn out above the pubes.—The patient (vide Fig. 1) is placed in Trendelenburg's position and the abdominal wall is incised from the pubes towards the umbilicus and as far above it as is necessary to permit of the extraction of the tumour. The peritoneum is caught on each side of the incision by several catch-forceps and a large compress is thrust in behind the tumour to isolate it and to protect the intestine, &c The fibroid is then drawn well up and out by means of the large fibroid-screw. Several other compresses are introduced at the sides above the pelvic brim to isolate the field of operation, to prevent the escape of intestine, and to protect the peritoneum from contamination by clots of blood or uterine mucus.

Second step: perforation of Douglas's pouch and seizure of the cervix.—If it has been easy to draw the tumour well out of the abdomen its removal should be rapid and simple. The vagina has, of course, been cleansed and long curved forceps are pushed by the assistant behind the cervix in the posterior cul-de-sac as high up as possible (*vide* Figs. 2 and 3). (A manœuvre, now neglected but followed by Dr. Doyen in his earlier cases and certainly of use to those unfamiliar with the operation, is to place at this stage a strong silk ligature through the peritoneum at about half an inch below the point made prominent by the forceps in the vagina. The peritoneum is opened at this point and the ligature enables its posterior border to be easily picked up at the close of the operation when the suture of the peritoneum is commenced.) Douglas's pouch is then incised. This is best done with scissors cutting longitudinally upon the point of the long curved forceps which then penetrate the peritoneal cavity and are widely opened by the assistant. The incision is extended a little on either side and the cervix is firmly seized by strong catch forceps, or, better still, by Doyen's special sliding tenaculum, and drawn well up, the assistant steadying the tumour by holding the fibroid screw firmly embedded in its tissue.

Third step: isolation of the cervix.—It is now easy to feel with the index finger of the left hand the strong lateral attachments of the cervix. Two cuts with the scissors laterally close to the uterine wall free the cervix from its relations to the lower part of each broad ligament, and being thus freed it is at once easily drawn further up and out. The anterior vaginal cul-de-sac now comes into view and the cervix is separated from it by the fingers or by the scissors, strong traction being made upon it throughout. The right forefinger separates the bladder with the greatest ease, the traction alone, thanks to the loose cellular tissue separating the bladder and uterus, often sufficing to liberate entirely the cervix and the uterus.

Fourth step: removal of the uterus.—Only the lateral vascular connexions now remain, to be simply and rapidly divided as follows. The left forefinger is passed above the superior border of the right broad ligament, through the vesico-uterine peritoneum and gently but rapidly strips off the right broad ligament which the assistant then seizes. The surgeon then cuts between the annexa and the uterus, thus entirely freeing the tumour on its right side. It is then drawn over to the left, the anterior peritoneal covering stripping off as this is done or, if not, separated by a few cuts with the scissors, and finally only adhering by the upper part of the left broad ligament, which is similarly cut, and the tumour and uterus are removed.

Fifth step: arrest of hæmorrhage.—The surgeon then seizes the broad ligament on his side of the patient (the left). The uterine and utero-ovarian vessels, which alone are now bleeding, are caught and ligatured, and if care has been taken to cut close to the uterine tissue only minor branches of these arteries will have been opened. The right and left appendages are now ligatured and removed and the pelvic cavity is sponged out. It only now remains to close the peritoneal cavity.

Sixth step: closure of the pelvic peritoneum.—The right vaginal commissure is picked up with strong dissecting forceps and a curved needle successively threads it, the retro-uterine peritoneum, the peritoneum of the tubo-ovarian pedicle and finally the peritoneum between that pedicle and the bladder. A medium silk ligature is passed through the eye of the needle and when drawn tight completely closes the peritoneum over the tubo-ovarian stump. The left side is similarly treated and a transverse suture between the two closely unites the retro-vesical peritoneum to that of Douglas's pouch. Any redundancy of peritoneum or tear should be carefully sutured. A dry compress again sponges out the pelvis and the operating table is placed horizontally.

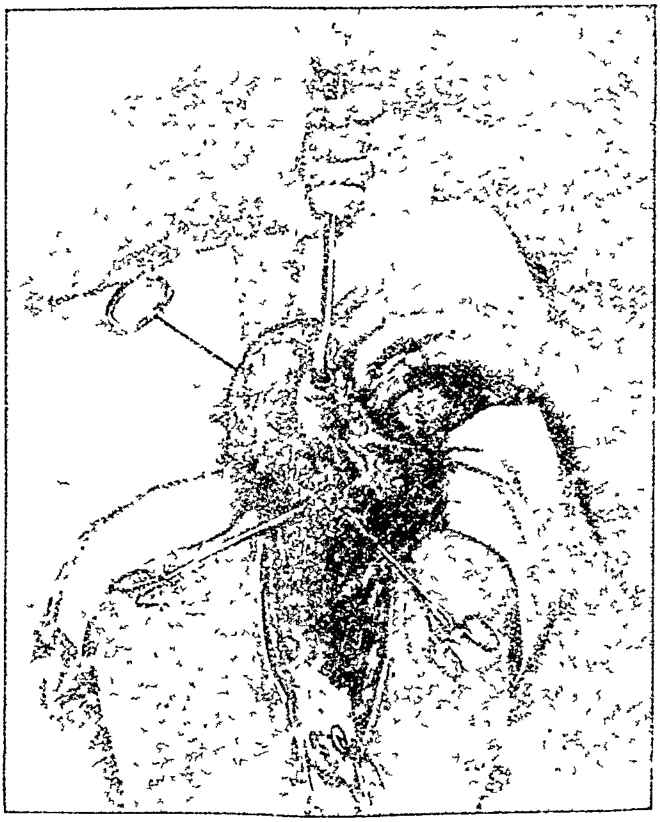
Seventh step: closure of the abdomen.—This is effected by a deep sero-aponeurotic layer with interrupted silk suture or continuous catgut and a superficial skin suture with silkworm or catgut. Thus it will be seen that while the tumour is rapidly removed much time is spent on the careful suture of the peritoneum and of the abdominal wall.

Remarks on Special Manœuvres.

1. *The broad ligaments.*—Frequently the broad ligaments are unduly short owing to their attachment high up on the lateral parts of the tumour and it is difficult to get the latter elevated well out of the pelvis. These tight bands, as it were, of the broad ligaments are at once felt by the index finger and may be caught either by the assistant or with long curved elastic forceps and cut through close to the uterus. It is rarely necessary to apply pressure forceps to the uterine surface. If necessary the left broad ligament is similarly treated.

2. *Hæmorrhage from the uterine artery during the isolation of the cervix uteri.*—This usually occurs while the cervix is being drawn up with the tenaculum, but the surgeon is prepared for it, and it is as easy to catch it with pressure forceps as to catch an artery of similar calibre, say, in an amputation of the breast. As the patient is in the Trendelenburg position and is more or less congested it is frequently of use to proceed with the removal of the tumour and then return to the ligature of the two uterine arteries which have served the purpose of a venesection.

FIG. 3



The result of further traction is seen in this illustration, where the cervix is entirely freed. The opened forceps are still seen in the vagina. (Plate XIV., No. 1, facing p. 459, Macnaughton Jones. From photograph lent by Doyen.)

3. *Difficulty in reaching Douglas's pouch on account of adhesions or a posterior sub-peritoneal fibroid blocking the pelvis.*—Dr. Doyen remarked upon this difficulty in 1892 and showed how slight were the changes which it was necessary to introduce into the technique. The tumour is drawn up as high as possible, any adhesions are separated, and if there are multiple posterior fibromata present the peritoneum and uterine tissue are incised and these fibroids easily enucleated with the fingers or the screw. If the posterior cul-de-sac remains inaccessible the forceps in the vagina are simply pushed towards the right broad ligament and the right lateral vaginal cul-de-sac is perforated as close as possible to the insertion into the cervix of the lower edge of the right broad ligament and the operation is proceeded with as in more ordinary conditions.

4. *Isolation of the cervix from the vagina before the abdomen has been opened.*—This is a manœuvre that considerably facilitates the operation, especially to those undertaking it for the first time. It is well, at any rate, during the preparation and toilette of the vulva and vagina to examine carefully the exact position and relations of the cervix. The

higher it is and the more difficult of access by the vagina the easier it will be to reach it from the abdomen. The lower and more normal it is the easier will be the preliminary circular incision of the mucous membrane *per vaginam*. Undoubtedly the most delicate step in the operation is the section of the lateral attachments of the cervix and of the mucous membrane of the posterior vaginal cul-de-sac, and when this is done as a preliminary step by the vagina the extirpation of the uterus by the abdomen is of the greatest simplicity.

5. *Drainage.*—Though not habitual it is sometimes well to drain Douglas's pouch, either after an exceptionally laborious operation or when the vagino-peritoneal wound has been plugged and not sutured. The best method is by a glass drain introduced from the most dependent part of Douglas's pouch into the vagina and covered externally by a small pouch of thin rubber or skin to collect aseptically any fluid that may thus drain.

6. *After-treatment.*—The patient is well purged on the second day, and sometimes on the first day, after the operation. If the temperature rises ice chopped in small pieces and placed in bladders is laid over the abdomen. I have yet to find the patient who did not find this soothing and comfortable. These are the two details in which the after-treatment differs from that followed in all laparotomies.

Paris.

BILATERAL RESECTION OF THE SUPERIOR CERVICAL GANGLION OF THE SYMPATHETIC FOR GLAUCOMA.

By H. WORK DODD, F.R.C.S. ENG.,
OPHTHALMIC SURGEON TO, AND CLINICAL LECTURER ON OPHTHALMIC MEDICINE AND SURGERY AT, THE ROYAL FREE HOSPITAL; SURGEON TO THE ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, ETC.

THE operation which I describe in this paper was performed upon a patient as a result of an article by Dr. Jonnesco of Bucharest which appeared in *La Presse Médicale*, June 8th, 1898. In that article Dr. Jonnesco stated that he had performed the operation of resection of the superior cervical sympathetic ganglion for glaucoma seven times and that at the time of writing the cases were old enough to enable one to judge as to the value of the procedure. The results claimed by him consist in an immediate and permanent fall in the ocular tension in all the cases, very energetic contraction of the pupil even in those cases previously iridectomised, disappearance of peri-orbital pains and cephalalgia when these existed, disappearance of the attacks in the irritative glaucoma cases, and very marked and permanent improvement of the sight in the cases where optic atrophy was not complete. This lessening of the ocular tension, due to resection of the superior cervical ganglion, is explained by the ablation of the ocular fibres of the sympathetic which traverse this ganglion before reaching the eye. These fibres are distributed to the iris, the uveal tract, the vessels of the eye, and the peri-bulbar muscular apparatus contained in the capsule of Tenon, &c. Their excitation, permanent or intermittent, peripheral or central, produces a collection of phenomena which is termed "glaucoma." Permanent or intermittent contraction of the arterioles produces an increase of blood-pressure from which arise extravasation and increase of the aqueous humour. Permanent or intermittent dilatation of the pupil draws the iris towards the iridian angle, which condition obstructs the canals or the zone of filtration and prevents or slows down the flow of the aqueous humour. The permanent or intermittent contraction of the peri-bulbar muscular apparatus compresses the emissary veins of the bulb and clogs the venous circulation of the eye whence arises dilatation of the intra-ocular veins. This being admitted one easily understands the mechanism by which the resection of the superior cervical ganglion produces decrease of tension and with this cessation of all the troubles of glaucoma. Dr. Jonnesco believes glaucoma to be central and not peripheral in origin. In suppressing the superior cervical ganglion the origin of the trouble is not removed, but the ways of transmission are destroyed. He thinks that this operation should be especially successful in its results in chronic irritative glaucoma and in simple chronic glaucoma. The foregoing is a brief summary of what I take to be Dr. Jonnesco's views on the subject.

It is an undoubted fact that iridectomy has been found to fail in most cases of the chronic forms of glaucoma and that we are now in a state of peculiar uncertainty as to the best treatment of this most troublesome and painful disease. If it be true, as Dr. Jonnesco states, that the removal of the [illegible] beneficial effect upon [illegible] s operation a means for [illegible] whose eyes under the [illegible] to worse. After taking all the above facts into careful consideration in consultation with my friend and colleague Mr. E. W. Roughton at the Royal Free Hospital, Gray's Inn-road, I *felt justified* in performing the operation in the following case which seemed to present the characteristics most favourable for trial.

The patient was a woman, aged 62 years, who had been under treatment for chronic glaucoma off and on for about 14 years at the Royal Free Hospital. During that time her vision had been steadily and slowly diminishing and she had never been free from pains in the eyes and "all parts" of the head. During this long time exacerbations occurred at intervals of about six months. While these exacerbations lasted her sufferings from pain in the eyes and head were extreme. She then saw "flashes of light," and though she did not vomit she was the subject of nausea. The symptoms had always been somewhat relieved by the use of eserine. In November, 1891, vision = $\frac{6}{12}$ in both eyes and she wore + 3 50 D. glasses for near work. In October, 1896, the R. E. vision = $\frac{6}{36}$; L. E. vision = $\frac{6}{60}$. In December, 1898, R. E. vision = $\frac{6}{24}$; L. E. vision = $\frac{6}{60}$. The fields of vision had very slowly contracted, this being most marked on the temporal sides. The tension had never been extreme, varying up to + 1 in either eye during the exacerbations. The patient had been the subject of dysmenorrhœa through most of her adult life. Two years ago she had hæmorrhage from the mouth (gastric ulcer?), but she had had no other serious illness. The patient was a milliner and had had for many years a successful business, but about 10 years ago it began to deteriorate and since then she had been in struggling circumstances. One of her sisters had had the left eye removed for "ulcers" and had had an iridectomy performed on the right eye for chronic glaucoma, for which condition she is still under my treatment. There was said to be gout in the family. The patient was a rather thin, white-haired, somewhat anæmic woman. The pupils were equal, regular, and small, but not contracted. The field of vision for the right eye for white was slightly contracted and more marked on the temporal side; the fields for red and green were still more conspicuously lessened. Vision = $\frac{6}{18}$. In the left eye the field of vision for white was decidedly contracted, especially on the temporal side. In the upper temporal quadrant there was a scotoma and the whole of the centre of the field was blurred and indefinite. Colours were indistinctly seen with this eye. Vision = $\frac{6}{60}$.

Ably assisted by Mr. Roughton I operated in the following manner. An incision about four inches in length was made along the line of the anterior border of the right sterno-mastoid muscle, beginning above at the level of the angle of the lower jaw through the skin and fasciæ. The anterior border of the sterno-mastoid muscle was then exposed and its fascia divided in the whole length of the wound. The border of the muscle thus shown was drawn back. Several lymphatic glands were then removed. The common facial vein was ligatured in two places and divided between near to its entrance to the internal jugular vein. The fascia below the sterno-mastoid muscle was then torn through and the sheath of the great vessels of the neck was opened. The artery and vein were carefully dissected apart and the vagus nerve was then searched for and found. It was then drawn forward by a retractor, together with the carotid artery, while the internal jugular vein was held backwards by another retractor. The cord of the cervical sympathetic nerve with the superior cervical ganglion was then found in the fascia at the bottom of the wound, from which it was carefully dissected out. The ganglion was seized in a strong pair of forceps and pulled forcibly downwards with a twist so as to tear out the nerve from as high up as possible. The nerve was then cut off at the lower angle of the wound and about one and a half inches of its length were removed, including the ganglion. The operation was then repeated in exactly the same manner on the other side of the neck. The wounds were closed with separate silk stitches and a wet gauze dressing was then applied. The anæsthetic employed at first was ether, but it was found necessary to change this to chloroform for the second operation on account of the engorgement of the veins of the neck produced by the ether. This operation is practically identical with that described by Dr. Jonnesco under the name of "pre-mastoid."

The patient's pulse was good during the first operation but became rather feeble in the course of the second. It was noticed that it became slower and more feeble when the vagus was forcibly retracted, and this was more marked on the left side. After returning to the ward the patient vomited a good deal and sweated freely, but the pulse was good and there was never any serious collapse. The day after the operation, with the exception of a certain difficulty in swallowing, a somewhat excessive amount of mucus in the pharynx, and an aching pain of a moderate degree in the neck and the sides of the head, the patient was as comfortable as could be expected under the circumstances. The pulse was good and the temperature was normal. The tension of the eyes was a soft normal and the pupils were small. Several days later the patient was practically well The difficulty in swallowing quickly disappeared. The pupils remained small and she stated that since the operation she had had no pain in her eyes. At least several months must elapse, however, before any decided opinion can be formed as to the success of the operation as regards the relief of the glaucoma.

This operation is undoubtedly a severe one and more so in that it is usually required on both sides of the neck. The proximity of the great vessels and nerves of the neck which have to be themselves handled and pulled apart necessitates the greatest care and a certain amount of general operative experience on the part of the surgeon.

The question naturally arises as to the risk and magnitude of the operation as compared with the severity and gravity of the disease for which it has to be performed. If such an operation does permanently and satisfactorily arrest the glaucoma, preserve the sight, relieve the pains, and restore the patient to even comparative comfort, then I consider it may be undertaken.

I have to thank Dr. F. Eddison and Miss M. M. Sharpe for assistance in respect to the notes of this case.

Harley-street, W.

TWO ILLUSTRATIVE CASES OF SINUS PYÆMIA WITH UNUSUAL RESULTS.

BY JAMES KERR, M.A., M.D. CANTAB.,
HONORARY SURGEON, BRADFORD EYE AND EAR HOSPITAL.

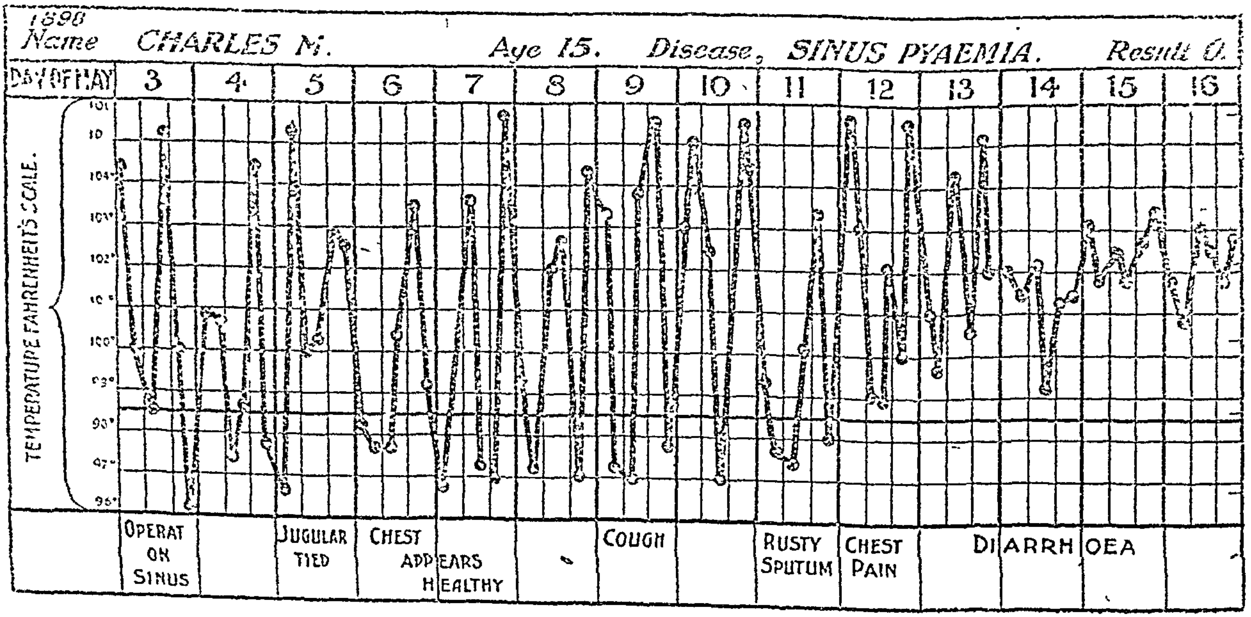
INCREASED attention is now being paid to aural diseases. The recorded mortality from otitis has increased from 5 to 25 per 1,000,000 in 20 years, between 70 and 75 per cent. of these deaths occurring in persons under 15 years of age, so that the suppurative ear disease so frequently neglected after the exanthemata is of serious import to life within a few years. Its import arises from extensions beyond the middle ear leading to abscess or pyæmia. Ten years ago these suppurative complications were looked upon as almost fatal; they are of the gravest import still, and one of the most formidable is sinus pyæmia. Two cases recently seen are worth recording; they are typical in clinical features, but unusual in the result. The treatment followed in both cases was by operative measures and the use of anti-streptococcic serum.

CASE 1.—A youth, aged 15 years, had suffered from chronic otitis for many years. Mastoid operation had been advised a year previously to his being seen by me on April 21st, 1898. There were acute exacerbation, pain, diffused swelling felt rather than seen over the right occipital and the parietal bones, loss of taste on the right side, and slight paresis on the right side of the face. The patient was admitted to hospital on the third day (April 25th). On the next day the right mastoid was explored. The antrum was continuous with a great smooth-walled cavity, which was filled with cholesteatomatous material. This was cleared out and a stinking abscess, which was found under the fascia over the parietal region, was disinfected. Some improvement took place, but there were rigors still, with a pyæmic temperature range of about 6° F. Some days later the sigmoid sinus was explored, when green pus was found. This was cleared out, the sinus was packed with gauze, and finally the jugular vein was tied. Ten cubic centimetres of anti-streptococcic serum were injected, at first once daily, then twice a day, but there was no improvement. The local infection was becoming generalised and there were great wasting and cough, and then chest râles and rusty sputum, pleuritic pains, steady increase of average temperature, general pyæmia, and offensive "typhoid" stools, with diarrhœa during the last ten days. Death took place on May 21st, within a month of the onset of the attack.

Post-mortem examination showed extension of the thrombus back from the obliterated part of the sinus and up the petrosal sinuses, general discolouration of bone, erosion and purulent lymph about the jugular foramen, several perforations punched out of the vein wall, and communication from the floor of the tympanum through the jugular dome, by which route infection seemed to have spread.

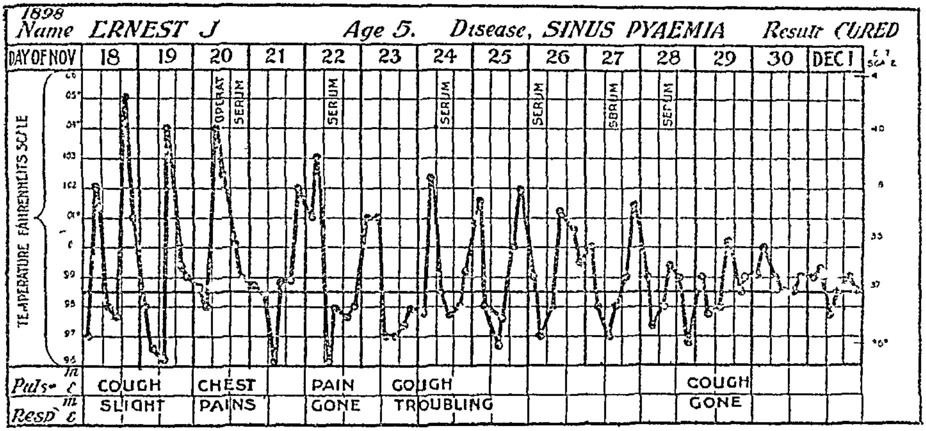
CASE 2.—The patient, a child, aged five years, had had ear trouble for a long time. The history was indefinite. For a fortnight recently there had been an abscess which had been opened by a medical man who sent the patient to the hospital, where he was admitted on Nov. 12th, 1898. The pulse-rate on admission was 104, the respirations were 28, and the temperature was 97·2° F. There was mental clearness, the tongue was coated with a thick, white, dry fur, and there was much discharge from the incision (Wilde's).

CHART 1.



Showing range of temperature.

CHART 2



Showing range of temperature and dates at which serum was given

Shotty cervical glands appeared on the side opposite to the wound only There was no thickening or tenderness over the jugular veins, the optic discs were normal, and there was no headache or pain During the night the pulse was 140 the respirations were 32, and the temperature was 103 6° F A diagnosis of probable left lateral sinus thrombosis was made An operation was performed on Nov 13th Bared bone was found for two inches back and above the incision The meatus had been stripped up, there was no discharging fistula Having chiselled deeply over the mastoid, pus was reached at a great depth The lateral sinus was thus fully exposed, it was solid and of a green blue black appearance (a drawing was made directly after the operation) The left jugular vein was tied and divided The sinus was now freely exposed till a healthy looking soft surface was reached Septic clot was freely scraped out till the bleeding at both ends necessitated plugging Both ends of the wound ultimately showed signs of being septic The pyæmic temperatures continued, but there were no rigors Cough began and there was rough breathing, and on Nov 20th there were acute chest pains Therefore further thorough exploration was made, the posterior end of the wound was opened up for an inch and scraped till a healthy area was reached The posterior wall of the middle ear was deeply chiselled till internal to, and below, the sinus a rudimentary antrum was found and cleaned out The whole tympanum was curetted and iodoformed The wound remained aseptic Serum injections (10 cubic centimetres) were administered about every 30 hours The patient's appetite improved except during 12 hours after each injection, the chest pains disappeared and the cough, which at first had been troublesome passed away within a week The temperature came slowly down to normal and the patient rapidly regained flesh and was discharged cured on Dec 10th

The mechanism of these cases is usually a chronic suppurative otitis with extension to the mastoid antrum and cells which discharge freely until suddenly, either from increased thickening of the mucous membrane or from slow thickening of the bone, the antral
ceases The first signal
inflammation from the
breaks its way through the ununited squamoso mastoid fissure but in others more often finds its way into cerebral sigmoid, or cerebellar fossæ The usual route leading to sigmoid sinus pyæmia is perforation from the antrum into the knee of the fossa, but in Case 1 the perforation appears to have followed a very unusual route in perforating the jugular dome When the local focus becomes diffused and the chest becomes affected recovery can scarcely be expected, yet this took place in Case 2 and probably was greatly aided by the use of the anti streptococcic serum With a rapid pulse and pyæmic temperature early exploration of the sinus should be made, and if it be found to be affected operative measures for the thorough removal of all septic material should be resorted to

HERBERT HOSPITAL, WOOLWICH.

TWO CASES OF ARTERIO VENOUS ANEURYSM CAUSED BY MAUSER BULLETS

(Under the care of Lieutenant-Colonel J T LEWTAS, I M S)

AN abnormal communication between an artery and vein is a fairly rare condition and it is rarer at the present time than formerly, for its most common situation was at the elbow, where venesection was usually performed The treatment of this condition advocated in the text books is based on the fact that the aneurysm which exists is traumatic in origin and therefore may be treated in the same manner as other traumatic aneurysms and so may be excised It is, however, by no means always necessary to excise these aneurysms, as Lieutenant Colonel Lewtas's interesting cases show, for a simple ligature sufficed The tendency, however at the present day is to excise the sac of aneurysms which are not traumatic in origin as well as those which arise from injury and the arguments advanced in support of this practice are that the harmful pressure exerted by the sac on neighbouring structures is more completely removed than by mere ligature of the artery and that the chance of recurrence of the aneurysm is much lessened It has also been found in practice that the probability of gangrene of the limb following the operation is lessened

CASE 1 —A private of the Argyll and Sutherland Highlanders when charging at Paardeberg on Feb 18th, 1900, was hit by two bullets, one of which passed through the right side of his chest and the other through the centre of his left patella making its exit at the back of the thigh, about the junction of the middle and lower thirds He soon recovered from both wounds but a varicose aneurysm developed between the popliteal artery and vein, for which he was invalided home On arrival at Woolwich there was a pulsating tumour in the left popliteal space of about the size gauze dressing was then applied. The anæsthetic employed at first was ether, but it was found necessary to change this to chloroform for the second operation on account of the engorgement of the veins of the neck produced by the ether. This operation is practically identical with that described by Dr. Jonnesco under the name of "pre-mastoid."

The patient's pulse was good during the first operation but became rather feeble in the course of the second. It was noticed that it became slower and more feeble when the vagus was forcibly retracted, and this was more marked on the left side. After returning to the ward the patient vomited a good deal and sweated freely, but the pulse was good and there was never any serious collapse. The day after the operation, with the exception of a certain difficulty in swallowing, a somewhat excessive amount of mucus in the pharynx, and an aching pain of a moderate degree in the neck and the sides of the head, the patient was as comfortable as could be expected under the circumstances. The pulse was good and the temperature was normal. The tension of the eyes was a soft normal and the pupils were small. Several days later the patient was practically well The difficulty in swallowing quickly disappeared. For a fortnight recently there had been an abscess which had been opened by a medical man who sent the patient to the hospital, where he was admitted on Nov. 12th, 1898. The pulse-rate on admission was 104, the respirations were 28, and the temperature was 97·2° F. There was mental clearness, the tongue was coated with a thick, white, dry fur, and there was much discharge from the incision (Wilde's).

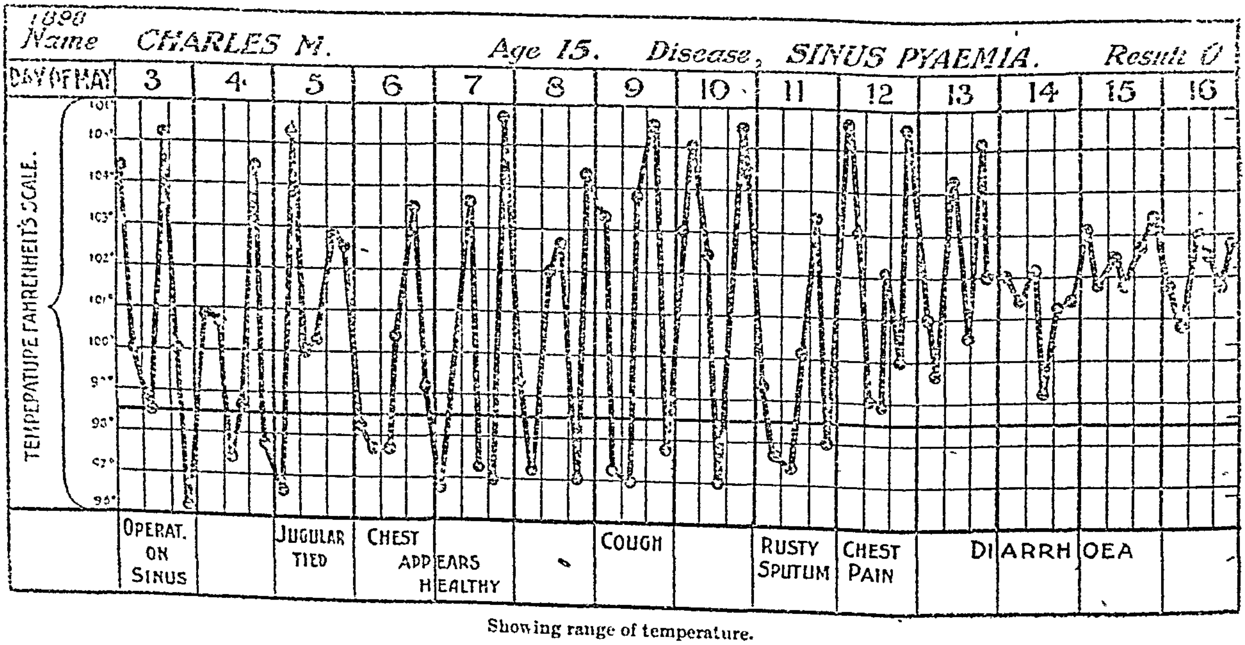
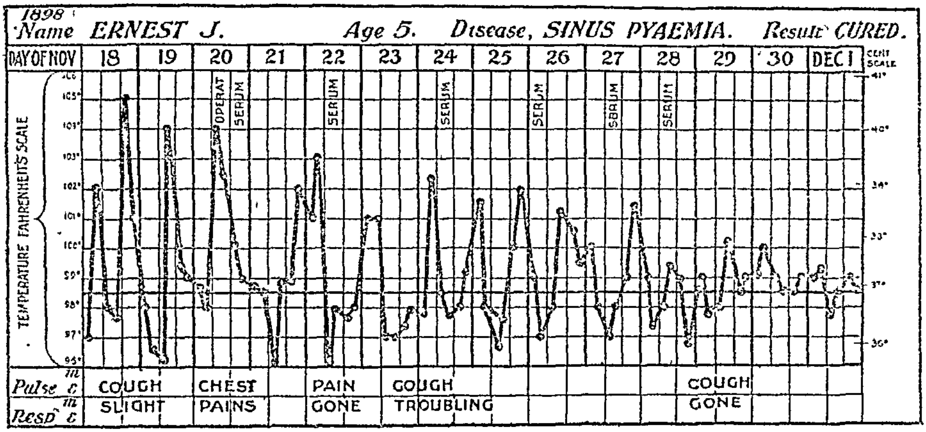
CHART 1.



Showing range of temperature.

CHART 2.



Showing range of temperature and dates at which serum was given.

Shotty cervical glands appeared on the side opposite to the wound only. There was no thickening or tenderness over the jugular veins, the optic discs were normal, and there was no headache or pain. During the night the pulse was 140, the respirations were 32, and the temperature was 103·6° F. A diagnosis of probable left lateral sinus thrombosis was made. An operation was performed on Nov. 13th Bared bone was found for two inches back and above the incision. The meatus had been stripped up; there was no discharging fistula. Having chiselled deeply over the mastoid, pus was reached at a great depth. The lateral sinus was thus fully exposed; it was solid and of a green blue-black appearance (a drawing was made directly after the operation). The left jugular vein was tied and divided. The sinus was now freely exposed till a healthy-looking soft surface was reached. Septic clot was freely scraped out till the bleeding at both ends necessitated plugging. Both ends of the wound ultimately showed signs of being septic. The pyæmic temperatures continued, but there were no rigors. Cough began and there was rough breathing, and on Nov. 20th there were acute chest pains. Therefore further thorough exploration was made; the posterior end of the wound was opened up for an inch and scraped till a healthy area was reached. The posterior wall of the middle ear was deeply chiselled till internal to, and below, the sinus a rudimentary antrum was found and cleaned out. The whole tympanum was curetted and iodoformed. The wound remained aseptic. Serum injections (10 cubic centimetres) were administered about every 30 hours. The patient's appetite improved except during 12 hours after each injection, the chest pains disappeared, and the cough, which at first had been troublesome, passed away within a week. The temperature came slowly down to normal and the patient rapidly regained flesh and was discharged cured on Dec. 10th.

The mechanism of these cases is usually a chronic suppurative otitis with extension to the mastoid antrum and cells which discharge freely until suddenly, either from increased thickening of the mucous membrane or from slow thickening of the b[illegible]nd discharge ceases [illegible] with violent inflamm[illegible] in children breaks its way through the ununited squamoso-mastoid fissure, but in others more often finds its way into cerebral, sigmoid, or cerebellar fossæ. The usual route leading to sigmoid sinus pyæmia is perforation from the antrum into the knee of the fossa, but in Case 1 the perforation appears to have followed a very unusual route in perforating the jugular dome. When the local focus becomes diffused and the chest becomes affected recovery can scarcely be expected, yet this took place in Case 2 and probably was greatly aided by the use of the anti-streptococcic serum. With a rapid pulse and pyæmic temperature early exploration of the sinus should be made, and if it be found to be affected operative measures for the thorough removal of all septic material should be resorted to.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

HERBERT HOSPITAL, WOOLWICH.

TWO CASES OF ARTERIO-VENOUS ANEURYSM CAUSED BY MAUSER BULLETS.

(Under the care of Lieutenant-Colonel J. T. LEWTAS, I.M S)

AN abnormal communication between an artery and vein is a fairly rare condition and it is rarer at the present time than formerly, for its most common situation was at the elbow, where venesection was usually performed. The treatment of this condition advocated in the text-books is based on the fact that the aneurysm which exists is traumatic in origin and therefore may be treated in the same manner as other traumatic aneurysms and so may be excised. It is, however, by no means always necessary to excise these aneurysms, as Lieutenant Colonel Lewtas's interesting cases show, for a simple ligature sufficed. The tendency, however, at the present day is to excise the sac of aneurysms which are not traumatic in origin as well as those which arise from injury and the arguments advanced in support of this practice are that the harmful pressure exerted by the sac on neighbouring structures is more completely removed than by mere ligature of the artery and that the chance of recurrence of the aneurysm is much lessened. It has also been found in practice that the probability of gangrene of the limb following the operation is lessened.

CASE 1.—A private of the Argyll and Sutherland Highlanders when charging at Paardeberg on Feb. 18th, 1900, was hit by two bullets, one of which passed through the right side of his chest and the other through the centre of his left patella making its exit at the back of the thigh, about the junction of the middle and lower thirds. He soon recovered from both wounds, but a varicose aneurysm developed between the popliteal artery and vein, for which he was invalided home. On arrival at Woolwich there was a pulsating tumour in the left popliteal space of about the size of a walnut, with the characteristic thrill of an arterio-venous aneurysm. An interval could be distinguished by the fingers between the tumour of the vein and the underlying artery. His chief complaint was of constant pain over the dorsum of the foot and lower part of the front of the leg. On May 23rd an incision was made over the popliteal space and the vein was tied above and below the aneurysm. The artery could not be tied at the same place as it lay deep upon the lower end of the femur and was obscured by oozing of blood. A second incision was therefore made in the usual situation for ligature of the popliteal artery at its upper end, and the artery was tied there. The patient made a good recovery, the tumour quite disappeared, and when he was discharged in August the pain in the foot had also almost gone, showing that it was chiefly due to pressure of the tumour on nerves.

CASE 2.—This case did not end so favourably. A private of the West Yorkshire Regiment was hit on Feb. 11th, 1900, at Monte Christo by a bullet which passed through the inner border of his right thigh above its middle. On arrival at Woolwich the patient was found to have a varicose aneurysm at the upper end of Hunter's canal. On May 31st the femoral artery was ligatured just above its communication with the vein, and as this stopped all pulsation in the vein it was decided to postpone ligature of the latter to a subsequent occasion if it should ever be necessary; such a procedure would, it was thought, interfere less with the circulation of the limb and would therefore be less likely to be followed by gangrene, which is so frequent a result of high ligature of the femoral. But a few days after the operation the foot became cold and mummified and there was no alternative but to amputate the limb through the condyles of the femur. From this the patient made a good recovery, and when discharged there was no sign of an aneurysm of the vein.

Remarks by Lieutenant-Colonel LEWTAS.—The practice of tying both artery and vein above and below these aneurysms and then dissecting out these appears unnecessarily elaborate and severe, and the simpler operation adopted in these two cases was quite satisfactory so far as the aneurysms were concerned.

ROYAL NAVAL HOSPITAL, PLYMOUTH.

TWO CASES OF BULLET WOUNDS.

(Under the care of Deputy Inspector-General H. T. COX, R.N.)

THE former of the following two cases is a good example of the value of suture for a divided nerve even when it is not possible to bring the two ends into exact apposition. In such cases, however, a good result is always doubtful and sometimes transplantation of a portion of nerve is advisable. In the second case an aneurysmal varix interfered seriously with the use of the limb. Any such interference is rather exceptional with this condition, but is more likely to occur in the lower than in the upper limb because the blood-pressure in the veins is greater in the former. For the notes of the cases we are indebted to Surgeon H. W. Gordon Green, R N.

CASE 1. *Fracture of the humerus with division of the musculo spiral nerve by a Mauser bullet.*—A private, aged 29 years, Royal Marine Light Infantry, H.M.S. *Powerful*, was wounded in the left arm by a Mauser bullet at Graspan on Nov. 25th, 1899. He was carrying his rifle at the slope when he received the injury. The bullet passed between the ring finger and little finger (as shown by slight skin wounds), struck the butt of his rifle, which was sent flying out of his grasp some distance away, grazed the palm of the hand, and entered the centre of the arm through the anterior and outer aspect of the biceps, fracturing the humerus and dividing the musculo-spiral nerve. He was admitted into the Royal Naval Hospital, Simon's Town, on Nov. 29th, where a radiograph showed extensive comminution of the humerus and lodgment of the bullet beneath the skin at the back of the arm. On Dec 4th the bullet was removed and was found to be a Mauser (ricochet) bent into a V shape. The bullet was probably bent on striking the brass-bound butt of the rifle, and it now adorns the man's watch-chain. On Jan. 10th, 1900, he was discharged invalided to the s.s *Simla* for passage to England. The fracture had united, a large amount of callus extending from two inches from the elbow joint to three inches from the upper end of the humerus having been thrown out. There was a fair amount of œdema of the forearm.

On March 5th the patient was admitted into the Royal Naval Hospital, Plymouth, under the care of Deputy Inspector-General H. T. Cox, R.N., with wrist-drop, complete motor and sensory musculo-spiral paralysis, with clamminess of the hand and wasting of the muscles. On the 20th, the patient having been prepared for an anæsthetic, the arm shaved and the skin antisepticised, chloroform and subsequently ether were administered. The arm being placed over the body a slightly oblique incision four inches in length was made half an inch behind the posterior border of the deltoid muscle which was defined, the intersection between the long and outer heads of the triceps was found, and the bone was exposed. The cicatricial tissue marking the track of the bullet could be easily traced down to the bone, and after much search the ends of the nerve were found, freshened, and sutured with catgut. Accurate apposition could not be obtained, about half an inch of the nerve having been destroyed, but on tightening the sutures there was a gap of only about a quarter of an inch. There was troublesome hæmorrhage from the upper end of the superior profunda artery in searching for the nerve. The muscles and skin were sutured, the wound was dressed antiseptically, and a rectangular splint was applied. The temperature reached its highest point (100·8° F.) on the 22nd and was normal on the 24th. On the 28th the sutures were removed and the wound was found to be soundly healed. On April 6th there was slight return of sensation in the back of the forearm and in the thumb. On the 18th galvanism was applied. On May 23rd the patient was discharged to 90 days' furlough. Sensation was completely restored and the hand had lost all coldness and clamminess. The muscles supplied by the musculo spiral nerve responded to the galvanic current and there was considerable increase in power in the extensors of the thumb, but wrist-drop still persisted.

CASE 2. *Aneurysmal varix of the femoral artery and vein caused by a Mauser bullet-wound.*—A private, aged 23 years, Royal Marine Light Infantry, H.M S. *Doris*, was wounded at Graspan on Nov. 25th, 1899, by Mauser bullets in the right thigh and leg. The wound of entry in the thigh was situated four inches below Poupart's ligament in the course of the femoral artery, the bullet passing directly back through the thigh, the exit wound being five and a half inches below the tip of the great trochanter. The wound of entry in the leg was situated one inch vertically below the tubercle of the tibia, apparently passing obliquely through that bone, the exit wound being at a level five inches lower down slightly to the outer side of the calf. The two bullets struck the man almost simultaneously as he was in the act of getting up from the prone firing position and they brought him to the ground. The distance from the enemy was about 300 yards, the Boers occupying a position on the face of a hill between 200 and 300 feet above the plain. There was considerable hæmorrhage from both wounds, saturating his clothing but not causing him to faint. Within a few minutes an officer of the Royal Army Medical Corps applied to the thigh wound the field dressing which he carried and five minutes later a corporal of the Royal Army Medical Corps bound up the wound in the leg. The patient was then removed by stretcher 500 yards to the rear, and thence by ambulance wagon one and a half miles to the dressing-station, where the wound in the leg was re-dressed, as it was still bleeding. From the dressing-station he was conveyed by ambulance wagon to Graspan Station Field Hospital, reaching there about five hours after being wounded. Here his wounds were dressed without hæmorrhage occurring and he remained until Nov. 27th, when he was sent by ambulance train to the Naval Hospital, Simon's Town, arriving there on Nov. 29th. On Dec. 7th the wounds had healed. A distinct thrill could be felt over the course of the femoral artery close to the upper wound and a loud buzzing bruit could be heard synchronously with the pulse. The condition of arterio-venous aneurysm was treated by rest, pressure, and elevation of the limbs, and on Jan. 10th, 1900, the patient was invalided home per s.s. *Simla*

On March 5th the patient was admitted into the Royal Naval Hospital, Plymouth, under the care of Deputy Inspector-General H. T. Cox, R.N. The limb was cold and slightly œdematous as compared with the other and it was practically useless as regards progression, the patient being unable to get about without the aid of crutches. The position of the wounds was as previously described. Pulsation in the posterior tibial and dorsalis pedis arteries was feeble. The bruit could be felt and heard about four inches above and below the scar of the entry wound, and it disappeared completely on compressing the femoral artery. There was no expansile tumour or enlargement of the veins, and the nutrition of the limb was good, with slight impairment of sensation. The patient stated that immediately on receipt of the injury and for four days following he lost all sensation in the limb, but that this had improved considerably since. On April 10th, the patient having been prepared for an anæsthetic, the thigh shaved and the skin antisepticised, he was placed under ether. The limb having been rendered bloodless by Esmarch's bandage and a tourniquet applied an incision five inches in length was made in the course of the artery through the cicatrix of the bullet-wound The track of the bullet led down to the sheath of the vessels, passing between the femoral artery and vein, a small amount of cicatricial tissue indicating the point of injury to the coats of the vessels, binding them and the sheath together, there being direct communication between the vessels at this point. The femoral artery was isolated and ligatured with kangaroo tendon half an inch above and below the wound in the vessels, the fibrous tissue joining the artery and vein being left undisturbed. On releasing the tourniquet no pulsation or thrill could be felt in the vein. The fascia and skin wounds were sutured with catgut and silkworm gut, the wound was dressed antiseptically, and the limb was enveloped in cotton-wool and elevated, warmth being maintained by hot-water bottles. The temperature never rose above 99 6° F. The limb and foot were quite warm and sensitive on the morning after the operation and the wound had healed and pulsation was felt in the posterior tibial on April 19th. He was allowed to get up on May 1st, from which date he made an uninterrupted recovery, and was discharged to duty on June 1st with full use of the limb.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

Adenoma of the Body of the Uterus.—Subcutaneous Symphysiotomy.—Exhibition of Specimens.

A MEETING of this society was held on Oct. 4th, Mr. ALBAN DORAN, the President, being in the chair.

Dr. HUBERT ROBERTS read notes of a case of Cancer of the Cervix associated with an Adenomatous Growth of the Fundus. The patient was a multipara, aged 38 years, who had advanced cancer of the cervix, the history dating from about four months before her admission. Except for discharge and hæmorrhage the patient was in good health. Though not a favourable case for vaginal hysterectomy this was performed on March 12th, 1900. The patient recovered well and was still without recurrence. The interest of the case was centred in the specimen, which showed a uterus with advanced cancer of the cervix associated with a curious growth in the fundus uteri, which proved on microscopical examination to be of an adenomatous nature and to have no connexion with the columnar-celled epithelium of the cervix. Mr. J. H. Targett and Dr. Walter Tate carefully examined the microscopical sections, which were prepared by Mr. Corrie Keep. Dr. Cosens prepared the excellent micro photographs shown. Dr. Hubert Roberts first discussed adenomatous growths occurring in the cervix uteri, the simplest forms being erosion, mucous polypi, and the follicular hypertrophy of pregnancy. There were also some rare cases of true adenomatous tumours, which were sometimes almost indistinguishable from columnar-celled carcinoma. As regards adenoma of the body of the uterus he considered that great confusion existed. "Endometritis," so-called, was a misleading term, for although a true septic endometritis existed, many conditions called "endometritis" associated with overgrowth were really adenoma, some apparently simple, othe[illegible] if they recurred. Reference was [illegible] which glandular elements inva[illegible] the uterus. Such growths [illegible] Mere curettings in adenoma [illegible] looked upon recurring adenoma- of the uterus in old women with grave suspicions.—The PRESIDENT said that it was clear that two different forms of new growth had developed in the same uterus. The tumour in the body was a pure adenoma according to its microscopical appearances, but to the naked eye it looked malignant. Much remained to be learnt about the earliest stage of cancer of the uterine body.—Dr. A. H. N. LEWERS said that he had met with a case presenting all the characters clinically of cancer of the cervix in which the microscopic examination merely showed large cavities lined by a single layer of columnar epithelium. Supra-vaginal amputation of the cervix was performed. For a time the patient remained well, but about a year after the operation the disease recurred in the scar, and before long there was a large typically malignant ulcer at the top of the vagina. As regards the cause why the uterus was fixed in advanced cancer Dr. Lewers believed the principal cause was extension of the malignant growth to the tissues in the neighbourhood. This seemed proved by cases where, as the impairment of mobility was only slight, an attempt was made to remove the uterus In several such cases the operation revealed infiltrated tissue beyond the uterus at the situation where the mobility of the uterus appeared to be checked.—Dr. W. S. A. GRIFFITH remarked upon the nature and significance of peri-uterine indurations in cases of presumably operable uterine cancer.—Dr. AMAND ROUTH said he believed that any definite growth developing from the lining membrane of the uterine body after the menopause tended to become malignant and should be treated as such. He instanced a case of recurrent papilloma, innocent microscopically, in which after hysterectomy the growth was seen to have deeply invaded the muscle of the uterus. He did not consider that hysterectomy was justifiable if the broad ligament or utero-sacral folds were indurated, for as all the disease could not be removed the growth was sure to progress —Dr. G. E. HERMAN could not agree with Dr. Griffith that fixation of the uterus in early cancer was often due to adhesions. He agreed with Professor W. J. Sinclair of Manchester that the usual direction of extension of uterine cancer was into the cellular tissue of the utero sacral ligaments. The situation of the induration due to spread of cancer in this direction was different from that of induration from pelvic peritonitis. In some doubtful cases in which he had commenced operation, but found that there was too much extension of cancer laterally for the operation to be completed, he had opened Douglas's pouch and found it free from adhesions. He had seen cases of large adenomatous polypoid growths in the uteri recurring again and again after removal; and the microscopical signs of such growths were distinctive; they were not solid, friable tissue like cancer, but pulpy, gelatinous translucent stuff. When such recurrence took place more than once he thought hysterectomy was indicated.—Dr. HERBERT SPENCER thought the report of the case a most valuable one. It clearly showed the association of a simple adenoma of the body with cancer of the cervix. He had no doubt that these adenomata had often been described as secondary deposits of cancer. Ruge and Veit's case ("Krebs der Gebärmutter," Fig. 34) was in his opinion erroneously so described. Cases of simple adenoma of the body had often been removed for cancer. He had met with simple adenoma in old women even recurring after curetting, and yet the patient remaining well and the uterus atrophying after as long as six years from the second curetting. The diagnosis between these cases and cancer was often very difficult —Dr. HUBERT ROBERTS, in reply, said he thought that in Dr. Lewers's case of suspicious recurrent adenoma of the cervix hysterectomy would have been a better proceeding than supra-vaginal amputation. He criticised Dr Griffith's remarks and thought it was impossible clinically to decide whether fixation of a malignant uterus was inflammatory or cancerous, and he considered that if the uterus could not be drawn down by traction with a pair of volsella owing to parametric invasion it was unsuitable for operation. He considered that vaginal hysterectomy was the best treatment for recurring adenoma of the body of the uterus in old women.

Dr. G. ERNEST HERMAN read a paper on Subcutaneous Symphysiotomy, pointing out the advantages of the subcutaneous operation especially as regards its simplicity, quickness, small risk of sepsis, insignificant hæmorrhage, absence of a gaping wound and of a subsequent scar. He urged that if the maximum benefit from symphysiotomy was to be secured it should be done under the most favourable conditions. It ought not to be postponed until the necessity for some kind of operative delivery had been demonstrated by the complete failure of the natural powers. The accoucheur should ascertain the size of the pelvis before labour and estimate also the size of the child. If he decided upon symphysiotomy it should be done at the most favourable time, and that was immediately after full dilatation of the os uteri. The frequency with which in contracted pelves the membranes ruptured prematurely would make the dilatation of the cervix with Champêtier de Ribes's bag usually advantageous. Dr. Herman pointed out that one risk at present inseparable from symphysiotomy was that of injury to the urethra; this was likely to happen in cases in which an attempt was made to deliver by symphysiotomy a child too large to be delivered in that way, and thus the pubic bones were excessively separated. This was to be guarded against by carefully estimating the size of the child beforehand.—Dr. Griffith described an easy method of ascertaining the relative sizes of the fœtal head and the maternal pelvis. The woman was made to sit on the edge of the bed at such an angle that the long axis of the fœtus was vertical. The fœtal head, if smaller than the pelvis, would then spontaneously dip into the cavity owing to the weight of the fœtus being free to act. He discussed the relative indications for induction of premature labour, symphysiotomy, and Cæsarean section in cases of contracted pelvis.—Dr. Lewers said he had seen some of the operations described in the paper and he regarded subcutaneous symphysiotomy as a great improvement on the method involving a large open wound. It was not applicable, however, in all cases. In his own case of symphysiotomy, for instance, there was a sort of "bite" or dovetail at the middle of the joint and a saw had to be used before the joint-surfaces could be separated. His patient had incontinence of urine for some weeks after the operation but ultimately recovered complete control in this respect and micturition was now quite normal.—Dr. Spencer thought the subcutaneous method recommended by Dr. Herman had advantages over the open method, but it was to be remembered that many cases of severe hæmorrhage from division of large vessels had been recorded and this had led some authorities to advocate the open method and packing the wound with iodoform gauze. Wounds in the vagina were also very apt to occur and if these communicated with extensive effusions about the pubes the danger of sepsis would scarcely be diminished by the subcutaneous method of dividing the joint.—Dr. Herman, in reply, said he was much interested in the method of ascertaining the relative size of the pelvis and child described by Dr. Griffith and hoped to put it in practice. He had included lacerations of the vagina in the injuries of the urethra of which he had spoken, for lacerations of the urethra usually affected the vagina also, and a laceration of the vagina so slight as not to reach the urethra was not important.

The following specimens were shown:—

Dr. H. Russell Andrews: Three specimens of Supernumerary Digits with Microscopical Section and Skiagrams.

Mr. J. H. Targett: 1. Pregnancy in a Rudimentary Uterine Horn; successful removal of gestation sac five months after full term. 2. Squamous-celled Epithelioma of the Body of the Uterus.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Specimen.—President's Address.

The first meeting of the nineteenth session was held at the West London Hospital on Oct. 5th. Dr. F. F Schacht occupied the chair. The minutes of the last meeting were read and confirmed and several new members were balloted for.

Dr. J. A. Mansell Moullin exhibited a Fibroid Tumour which, with the pregnant uterus, he had removed by subperitoneal hysterectomy. The patient, who was aged 25 years, had been married for four months. She stated that she was three months pregnant, but she presented a swelling in the abdomen resembling a seven months' pregnancy. She complained of severe pain in the left ilio-hypogastric region which commenced suddenly. There were considerable distension, great tenderness, feeble pulse, and collapse. As the patient grew worse Dr. Mansell Moullin determined to explore the abdomen. He opened it in the middle line by a long incision extending above the umbilicus. The tumour was at once seen, and on its summit was found a soft spongy mass of dark appearance with the peritoneal covering ruptured over it to the extent of about four inches. The operation was completed by removing the whole mass and together with it the uterus containing a four months' fœtus and the placenta. The patient made a very good recovery. The tumour was found to be an immense fibroid growing from the back and the upper edges of the uterus. It was sub-peritoneal and of such a size that it reached above the umbilicus. The uterus could be made out about eight inches lower down by means of the Fallopian tubes. The top of the tumour had sloughed and had broken through the peritoneal coat Dr. Mansell Moullin thought that this case illustrated well one of the many dangers that women with fibroids were exposed to. He said that he was unable to understand the mental attitude of a certain school which inculcates a "do-nothing' policy." Without an operation the patient in this case must have died. She was now spared the tremendous risk which she incurred by becoming pregnant.

Dr. F F. Schacht, the newly elected President, then delivered his address on the Early Treatment of Abdominal Symptoms. After thanking the members for the honour which they had done him by placing him in the chair, he alluded to the fact of his having been the first secretary with Mr. C. R. B. Keetley (the founder of the society) during his presidentship and to his now occupying the chair as a sort of evolutionary development from that position some 18 years ago. Other presidents of this and kindred societies had in their various addresses sketched the advance of every branch of medicine and surgery during the last 50 years. Among those were included the surgical triumphs in the domain of abdominal surgery. During the life-history of the society many fashions in abdominal surgery had arisen and passed away, or sunk to their proper levels, but these triumphs led occasionally to the neglect of the earlier clinical symptoms and their medical prevention. The surgeon's familiarity with the peritoneum had taught them to differentiate and realise many affections, but the clinical symptoms were much the same as of old—vomiting, constipation, diarrhœa, raised temperature, increased pulse-rate, pain, and tenderness. All these were most valuable as symptoms, but yet in many cases they were individually so uncertain in their manifestations that a large proportion of cases must remain of doubtful diagnosis in the early stage. As, however, many serious complications might arise unexpectedly if all possible precautions were not taken, a uniform and systematic method of treatment ought to be adopted from the very beginning in all cases of abdominal disturbance. The wonderful healing power of the peritoneum when left to nature and the process by which this was best attained were then discussed, with a view to showing that rest, mechanical and physiological, should be the object aimed at. Although this appeared to be a truism and was agreed to by all in advanced cases when the damage was done, it was clear from the number of cases of neglect seen daily that in the early stages sufficient care was not given either by the public or the profession to the essentials of rest. Dr. Schacht proceeded to urge that all cases of doubtful abdominal symptoms should be treated in a uniform manner—i.e., by absolute rest in bed, restricted fluid diet, the avoidance of all aperients, and the administration of small doses of opium, preferably hypodermically administered. Illustrative groups of cases—such as gastric ulcers, appendicular inflammations, obstructions, twisted ovarian pedicles, ovarian and tubal inflammations, including ruptured tubal pregnancies—were cited to show what a long list of abdominal troubles were seriously affected by this question of early care, even if they did eventually require the surgeon's interference. The constant reiteration in previous histories of wasted early opportunities had so struck him that he felt that their increased knowledge had, perhaps, developed a new danger and that there was apparently a liability to overlook medical prevention because of the familiarity with surgical cures The public must ultimately be guided by the profession and must be taught that prompt and strict treatment of a uniform character, if applied in the early stages of any abdominal attack, would shorten many an illness, would lessen its gravity, and would diminish the necessity for surgical interference.

A vote of thanks to the President for his address was proposed by Dr W. Travers and seconded by Mr. F. Swinford Edwards.—The President then replied and the meeting adjourned.

Reviews and Notices of Books.

A Text-book of Medical Treatment, Diseases, and Symptoms. By NESTOR TIRARD, M.D., F.R.C.P. Lond., Professor of the Principles and Practice of Medicine, King's College, London; Physician to King's College Hospital; and Senior Physician to the Evelina Hospital for Sick Children. London: J. & A. Churchill. 1900. Pp. 692. Price 15*s.*

IN most text-books on practical medicine the etiology, symptoms, and pathology are dealt with in detail, but the subject of treatment is considered only in general terms, thus affording little help in practical work; a desire is therefore felt by the student for a book in which treatment holds the primary place. Several such works have been published and the volume now before us is one of the latest additions to the number. Dr. Tirard has attempted something more, however, than a treatise on treatment only. The various diseases are described *seriatim*, the sequence of the chapters resting chiefly on an anatomical and physiological basis. Under the head of the different maladies the main symptoms are described, stress being laid on those which afford indications for treatment. Similarly, with regard to the causes and complications of certain morbid conditions, attention is directed to those which call for prophylactic or remedial measures. The student, in studying this work, in addition to receiving valuable hints and suggestions with regard to therapeutics, will be able to refresh his memory and to add to his knowledge of the symptoms of diseases.

Throughout all the chapters numerous prescriptions are given culled partly from the author's own experience and partly from the pharmacopœias of the London hospitals.

The various disorders of the circulation are first considered and the treatment suggested is sound and up to date. We would draw the reader's attention to the remarks on the use of digitalis in aortic disease, a subject which is always one of difficulty to the junior practitioner. Very instructive also are the observations on the treatment of chlorosis, a condition which not uncommonly is somewhat rebellious to treatment. We are unable to find any reference to the addition of iodide of potassium to iron salts, a procedure often productive of satisfactory results.

Three chapters are devoted to the therapeutics of disorders of respiration. In describing the treatment of tuberculous laryngitis sufficient stress is not laid on the use of strong solutions of lactic acid, which has frequently met with great success. The sections devoted to "Asthma," "Pneumonia," and "Reflex Cough" will also repay perusal.

The consideration of the diseases of the digestive tract occupies six chapters and a large amount of information is afforded. The chapters are sub-divided into sections for convenience of reference. The one devoted to "Organic Stricture or Chronic Obstruction of the Œsophagus" contains an excellent account of the procedures which may be adopted in that very troublesome and painful affection, and minute instructions are given for the preparation and administration of nutrient enemata. The consideration of acute and chronic gastritis and of gastric ulcer constitutes one of the best sections of the book. All these conditions are frequently met with, yet the student entering on the final stages of his medical curriculum will be frequently puzzled when asked to give minute instructions as to the treatment of a case of chronic gastritis or of a case of dyspepsia. He will suggest "Mist. gent. alk." or "Mist. bismuthi," but when requested to give the ingredients and necessary modifications of these standard mixtures he will most probably be at fault. In reference to the diet requisite for such cases, also, he would find it very difficult to put into writing a detailed diet chart containing the nature and quantity of the daily food. It is in reference to points such as these that a book of the nature of the one now under review is of such value. The use of lavage is recommended in some cases of chronic gastritis, especially when the morbid condition is suspected to be due to alcoholic or some other dietetic excess, and the method of carrying out the procedure is plainly described.

The principles involved in the treatment of diseases of the liver, kidney, and nervous system receive their due amount of attention, as do also the various specific infectious diseases.

Two chapters are devoted to the treatment of tuberculosis. The pulmonary form is naturally taken as the chief one coming under the notice of the practitioner, tuberculosis affecting other viscera being considered only as complications of what is ordinarily called pulmonary phthisis. The "open-air" method is fully described, but Dr. Tirard abstains from enthusiastic praise. He says: "It is not claimed for the open-air treatment that it is an infallible cure or that it will serve to prevent the extension of tubercle to other organs; but it is asserted, and apparently with justice, that in a large percentage of patients improvement will follow the adoption of this system; and there seems to be but little reason why establishments for the open air treatment of phthisis should not become part of the health arrangements of every town."

The book concludes with three chapters on the treatment of "Constitutional Diseases," including rheumatic fever, gout, rickets, and diabetes.

We have perused Dr. Tirard's book with much pleasure. The manner in which it is written is pleasing and attractive and, as we have already said, the instructions given for the treatment of the various diseases are sound and reliable and the student should have no difficulty in following them.

The Care of the Child in Health. By NATHAN OPPENHEIM. London: Macmillan and Co., Limited. 1900. Pp. 308. Price 5*s.*

THIS is a readable volume in which the author describes in detail the care required in rearing infants and young children, offering much good advice as the result of his experience. The book will prove useful in diffusing knowledge of scientific principles and common sense, which appear to be much needed among mothers. The author warns mothers against feeding children with "pungent and aromatic spices, preserved, pickled, and desiccated articles," further pointing out that "salads, pickles, beer, and wines, &c.," are unfitted for a child aged three years. Various ideas are expressed as to a woman's duties and as to the ideals and the aspirations of womanhood, which in some cases lead to the desire for public and laborious positions rather than for a domestic and social sphere of usefulness. Such a change may be gradually accomplished by women for themselves but should not interfere with the true well-being of women and the development of healthy well bred children. The chapters on health in pregnancy and in confinement, as well as that on the infant's outfit and nursery, are useful and give good guidance. Some of the details as to dress are original and full of common sense, while the expectant mother is wisely urged not to give way unnecessarily to habits of indolence or to apprehension of "maternal impressions" hurtful to the child. When speaking on the care of infancy there is a marked absence of description of the infant, and no instruction or encouragement is given to the mother in observing the conditions of developmental growth and the evolution of brain action such as indicate healthy progress, or the need of special care and advice, this seems to be an omission of importance. The mother's own observations of the growth of her infant's body and the evolution of the brain would prove a strong incentive to maternal care, affording an additional interest and self-acquired knowledge from experience as to health and growth day by day. The subject of infant feeding naturally occupies much space, and the proper use of the feeding-bottle and the preparation of milk foods affording appropriate diet are described in detail, while the dangers arising from the employment of an exclusive diet of sterilised milk are pointed out. The recommendation to add lime-water to the milk is in accordance with established practice; this helps towards neutralising acidity, but does not usually suffice for that purpose. Human milk has a slightly alkaline reaction; normal cow's milk is either neutral or slightly acid in reaction, and when supplied to the house it is usually acid in a degree not neutralisable by lime-water. Mothers are advised as to their health, exercise, and diet, but are not, we think, sufficiently urged to adapt their habits to the necessities of lactation and to use the natural supply for the benefit of the child, supplemented if need be by bottle-feeding. It is curious to find among the list of fat foods "sweet oil, olive oil, and some cereal oils"; such vegetable products are laxatives, not foods. It also appears of doubtful usefulness to mention to mothers a number of patent foods without explaining their uses and dangers The chapter on Sleep is good. It would be well if parents learned to observe the infant during sleep, the appearance of the face, and those transient and often asymmetrical smiles which may precede convulsions, as also the hands and twitching fingers accompanied by tooth-grinding which indicate absence of a full condition of brain rest. Education is dealt with in the abstract rather than by pointing out the natural brain faculties which the mother should study to exercise, such as imitation of initial sounds and speech, the use of the hands and their control through the senses. We do not agree with the author that the sense organs are too immature for early culture; a child under three years of age may receive impressions of colour if care is taken to present appropriate coloured objects; the naming and matching of the colours may be left for later training. This and other matters should not be left to chance experience; early impressions afford material for later mental acquisitions. Defective children are briefly described; here in particular the mother's habits of observation will help her to cultivate the special needs of the child.

Sewage and the Bacterial Purification of Sewage. By SAMUEL RIDEAL, D.Sc. Lond. London: Robert Ingram. 1900. Pp. 278. Price 14s.

THIS book has appeared most opportunely. Now that the purification of sewage has virtually passed from chemical methods to bacteriological methods the series of practical investigations that have been made on all sides needed crystallising into a *résumé* in which the present position of the subject could be seen at a glance. Dr. Rideal thinks that such a *résumé* would be acceptable to a wide class of readers in this country. We not only join him in this view but congratulate the wide class of readers on the fact that Dr. Rideal has undertaken the task. A *résumé* was decidedly in demand and Dr. Rideal has successfully supplied it in the volume before us. The very title of this work is surely a sign of the times and it is a remarkable fact that what must be regarded as a standard work upon the subject relates incidentally only to the methods of purification of sewage by chemical means, being devoted rather to a detailed and historic account of the life processes of purification—i.e., bacterial methods. We did not think that the views which we expressed 10 years ago would so soon be realised and that the unscientific and anti-utilitarian methods of treatment by chemical precipitants would by the end of the century be banished in favour of more rational methods depending upon the purifying action of microscopic agents. We use the word "rational" advisedly. Chemical treatment did not utilise the nitrogenous constituents of sewage, whereas bacterial methods promised to bring about the long-searched-for ideal, the conservation, as Dr. Rideal puts it, of the valuable constituents of sewage. The food question is very closely related to the sewage problem. The two subjects are adjacent, so to speak, in the maintenance of the cycle of existence, for it should be possible that excreted matters should be so appropriated by plants as to present the original offensive materials in a new and inoffensive shape in the form finally indeed of human and animal food. Hence the logical conclusion that by discharging human excreta into the sea and so entailing an enormous loss of nitrogenous constituents the land will be ultimately starved, and if the land then the plant, and if the plant then the animal. Sir William Crookes did a great service when he calculated that in the sewage and drainage of towns we hurried down to the sea fixed nitrogen to the value of £16,000,000 per annum. Though Liebig and others had anticipated that such a waste would lead to serious impoverishment, yet we have to thank Sir William Crookes for reminding us of this possibility in such forcible and practical terms. The point, however, which we would emphasise is that chemical precipitation gave no hopes after exhaustive experimentation that the valuable constituents of sewage would be realised by this method. It is true that chemical methods cleansed the sewage and stopped it from putrefying and from becoming offensive and a source of pollution to our water-supplies. So far the method was commendable, but mainly from the purely sanitary point of view and not from the economical standpoint. If we could convert the whole sewage in the United Kingdom into nitrates by bacterial methods we should derive, according to Mr. Scott Moncrieff, a revenue of £14,000,000 per annum, which is a recovery approaching in value the loss which Sir William Crookes estimated as occurring annually in the output of sewage and drainage of our towns. And this enormous waste may be obviated by micro-organisms. In this instance, at any rate, we must surely modify the cry, "Sterilise, sterilise," in favour of the cry, "Nitrify, nitrify." It may seem remarkable that the elaboration of bacterial methods applied to the purification of sewage has been slow, but when all the aspects of the problem are carefully considered it will readily be understood why we have not yet mastered all the details. It is on these details that Dr. Rideal's work is most valuable and instructive. There are all sorts and conditions of sewage to be met with in different parts of the country having different degrees of suitability for treatment bacterially, but so energetically has the practical study of the subject in all its aspects been carried on that we do not doubt that sooner or later the bacterial treatment of sewage will be universally applicable and universally successful.

It is now established in many places where large quantities of sewage are being treated that the effluent from the bacterial method is in every way satisfactory, but in spite of this there remains a requirement of the Local Government Board that the effluent must be passed through the land before it is discharged into a river or stream in accordance with the enactments of the Rivers Pollution Prevention Acts. The Local Government Board consider that the requirements of those Acts would be contravened unless the sewage is so purified. As Dr. Rideal points out—and we agree with him according to our observations of several bacterial installations in this country—the insistence on final land treatment is decidedly a mistake when purification is the main object—where a proper process is used no further purification will be necessary. Indeed, it is stated in many instances, and particularly at Hampton, that an originally good effluent suffers great deterioration by subsequent passage through the land. This requirement of the Local Government Board is to some extent a hindrance to the adoption of bacterial methods, since, *inter alia*, the question of a land-site convenient for the discharge of the purified effluent has also to be taken into account in addition to its suitability for bacterial beds Of course, this regulation was established before the present degree of purification of sewage by bacterial agencies was arrived at. Representations to the Board were accordingly made upon this point and this action resulted in the appointment of the Royal Commission upon Sewage in 1898, whose verdict we still await and probably shall have to await for some time on account of the great scope of the subject of inquiry. The delay, we fear, cannot be avoided, but until the conclusions of the Royal Commission are made public there is little doubt that the progress with bacterial methods will not be so rapid as is desirable. We feel confident, however, that the conclusions of the Royal Commission, as Dr. Rideal puts it, "will be in accord with those obtained from the experiments which have now been carried out on a sufficiently large scale to establish the safety of embarking on the treatment of sewage on bacterial lines for even the largest centres of population." Certain practical difficulties we all must admit have yet to be encountered, but we are sanguine that these will be overcome.

Dr. Rideal's book is most instructive on all the points connected with the bacterial treatment of sewage and its publication is, as we have said, timely and calculated to assist in attaining a complete solution of a very old and vexatious problem. We congratulate him on this (in our opinion his most important) contribution to the literature of sanitary science.

LIBRARY TABLE.

Glutton or Epicure. By HORACE FLETCHER. Including Nature's Food Filter, or When and What to Swallow, and What Sense? or Economic Nutrition. Chicago and New York. Herbert Stone and Co. Pp. 128.—This little book appears to be the outcome of some reflection and personal experiment on the part of a very benevolently disposed American gentleman. The author's aim is so altruistic and the means he recommends are on the whole so well advised that we are loth to cavil at his occasional logical and physiological mistakes. The preface states that "these studies have been pursued with the view to suggesting simple formulæ whereby busy persons may conserve physical health as an aid to harmony and happiness by preventive means." The simple formulæ alluded to may be gathered from the pages of the book to be "eat slowly" and "chew all things." For the great point that Mr. Fletcher seems to make is that most people eat a great deal too fast, that they get consequently comparatively little nutriment from a needlessly large food intake, and that they suffer many digestive troubles. These are truthful propositions, and Mr. Fletcher in preaching mastication is no more wrong than was the late Mr Gladstone who practised 33 bites to every mouthful. Mr. Fletcher insists also upon the chewing of liquids—a consummation that appears to us difficult of achievement. Honest endeavours in this direction would, however, no doubt guard against the swallowing of injuriously hot fluids. That such chewing would rob intoxicating liquors of their effect we cannot believe, and the experiment in this respect alluded to by Mr. Fletcher is one of those in which we do not recommend his readers to follow their adviser at any length. As an instance of experimental enthusiasm we may quote a passage. "The author has found that one fifth of an ounce of the midway section of the garden young onion, sometimes called 'challot,' has required 722 mastications before disappearing through involuntary swallowing. After the tussle, however, the young onion left no odour upon the breath and joined the happy family in the stomach as if it had been of corn-starch softness and consistency." It must not be supposed that Mr. Fletcher's creed often demands a perseverance of this magnitude, for, as he points out, with good food and good cooking comparatively short mastication soon induces involuntary swallowing. On the whole, readers of slight medical knowledge will find much profit in this little book from its quaint and striking directions to a leisurely and moderate manner of feeding.

The Diagnosis and Treatment of Syphilis. By TOM ROBINSON, M.D. St. And., physician to the Western Skin Hospital. Second edition. London: J. & A. Churchill. 1900. 8vo. Pp. 138. Price 3*s.* 6*d.*—We must confess that we do not understand the author's preface, where he tells us that "there seems no necessity, though doubtless much need, of making any substantial alteration in this edition." The progress that has been made in our knowledge of the disease since the first appearance of this work should have been recorded. The author tells us that he abolishes the terms "secondary" and "tertiary" and includes all the manifestations after the initial lesion in the term "sequelæ of syphilis" This is surely an utter misuse of the word sequela, which should be applied to signs and symptoms persisting after the disease itself has come to an end. On the whole a very fair account is given of the chief manifestations and treatment of syphilis.

ASYLUM REPORTS.

Joint Counties Asylum, Carmarthen (Annual Report for 1899).—The average number of patients resident during the year was 630 and comprised 314 males and 316 females. During the year 109 patients were admitted, 49 of these being males and 60 females. Of these 42 males and 52 females were first admissions, the rest being re admissions. The accommodation remaining the same as in the previous year, there were in residence 32 more patients than before, so that no vacant room now exists for the reception of out-county cases. At the isolation hospital the defective structure of the wall on the west side has for years been a source of trouble. Dr. E. Goodall, the medical superintendent, points out in his report that "a thorough overhauling of the defective parts will be desirable before the building comes into use as a permanent accommodation." Among the admissions is described a case of "moral insanity"—viz, a young girl admitted for the fourth time. "There being no defect or derangement of mind upon which a certificate of detention in an asylum could be returned she could not be kept here. This girl is a source of great trouble at home, but is neither mad enough to be in the asylum nor bad enough to be in gaol, and is probably best suited for a reformatory." One of the cases of acute mania occurred in a man, aged 73 years, and for the first time He passed through an attack which would have severely tried a man in the prime of life, and left quite well after a short residence in the asylum. Among the admissions the cause of insanity was traceable to heredity in 35 cases, alcoholic excess in 20 cases, recurrence of previous attacks in 16 cases, senile decay in six cases, domestic unhappiness in six cases, epilepsy in five cases, love troubles in four cases, privation in four cases, and the menopause in four cases Drink was responsible for rather more than 21 per cent. of the cases admitted. Of the admissions 21 were suicidal and 20 were dangerous. During the year 21 cases—viz., 10 males and 11 females—were discharged as recovered, or 3 3 per cent. of the average number resident. The deaths amounted to 46—viz., 25 males and 21 females—or 6·1 per cent., as calculated on the same basis Of the deaths one was caused by Landry's paralysis, two were due to influenza, two to colitis, three to renal disease, three to general paralysis of the insane, four to pneumonia, four to cerebral atrophy, seven to cardiac disease, and 11 to pulmonary phthisis. Typhoid fever has been absent since the outbreak of 1897. For the prevention of the high percentage of deaths from phthisis isolation and open-air treatment in separate blocks are regarded as highly desirable, and it is hoped that these will be provided for in the future. The farm and garden account shows a credit of £190 and the live stock have been free from disease.

THE LANCET.

LONDON: SATURDAY, OCTOBER 13, 1900.

The whole history of bubonic plague, as also does the testimony of recent events, points to the fact that the disease steals across the world mainly by unknown channels. It is true that when by the aid of little coloured flags we indicate upon a map the advance of any given pandemic wave we are able to follow its diffusion and the trade route by which it travelled; but when we investigate its progress from point to point we find, generally speaking, that the disease has been present in a town or country long before it was either officially or unofficially recognised. It is this attribute of plague—and for the matter of that of certain other exotic diseases—which has dealt the death-blow to quarantine. In this country we have long since recognised that all attempts to keep plague or cholera out of our islands, assuming the disease to have taken upon itself the truly epidemic garb, are likely to prove unavailing; and hence we have determined to rely largely on the internal machinery of the public health service. At our ports we have what we are pleased to term our first line of defence, but we endeavour to provide that everything which passes through this line shall be carefully labeled with its name and address; in short, the first line of defence is part and parcel of the whole fortification system, and if it plays us false the inland forts are taken by surprise. Within the last few days our outworks at Lynn and along the banks of the Tyne have apparently failed us; indeed, as far as we can see, even the lines of communication have broken down, and the brunt of the attack has devolved, in the first place, upon a medical practitioner, and in the second upon the medical officer of health in a rural district in South Wales These are serious facts, and the Local Government Board have taken the opportunity—we trust it is the psychological moment—to issue a "Plague Memorandum" dealing with "administrative considerations" and with "the symptoms of plague." The document is a model of reasonableness and simplicity, short and to the point. We are encouraged by it to believe that "the plague will not readily fasten upon that section of our population which is properly housed, cleanly, and generally in a sanitary sense well to do; that rather it will especially affect, if it obtains foothold in one or another district, insanitary areas such as are peopled by the poorest class, and where overcrowding of persons in houses and dirt and squalor of dwellings and of inhabitants tend to prevail." Here is the key-note for our sanitary authorities throughout the country, and it is a matter of national concern that they shall respond to the call. It is, we think, probable that the immediate danger is small; but the plague has assumed pandemic proportions, and no small degree of responsibility will rest on the sanitary authority which, in face of the obvious danger of the near future, elects to leave its slums as they are or neglects to see to the working of its administrative machinery. The memorandum here in question takes typhus fever as the type of the disease with which plague may be best compared, and in this it is doubtless right. But let us not be beguiled into believing that because typhus fever is not with us we shall therefore remain free from plague. The latter disease is awake throughout the world; typhus fever is apparently asleep—for the time. Unfortunately, the individual members of our sanitary authorities are apt to leave their consciences too much in the hands of their clerks, but we should be glad to be able to believe that on this occasion the members themselves would read the memorandum and see that the provisions generally are acted upon. The symptoms of plague are tersely set out and the reader is warned as to the danger to be expected from the slight or "ambulant" forms of the malady. Accompanying this document there is also another, embracing directions for obtaining and forwarding for bacterioscopic examination material from suspected cases of plague, whether in the living patient or in the dead subject. The material, which will be examined without cost to the local authority, is to be forwarded to Whitehall by the medical officer of health. So, too, the Local Government Board, with a truly parental foresight, has provided itself with a supply of Mr. Haffkine's prophylactic, and the medical officers of health of districts actually invaded by plague may procure from the Board a limited amount of this material. It now remains for the local authorities to support these efforts made by the central authority with a view to meeting the necessities of the situation.

◆

He who can enter the temple of Æsculapius without reverence would do better to stay outside altogether. The mystery of life, the almost equal mystery of suffering and disease, the ever-expanding knowledge that comes to us of the range of suffering occurring in the creation, the discovery of means whereby this suffering may be at least partially controlled, and the pathetic cry of all sentient beings for the extension of such means constitute a theme which must command the respect of all but the frivolous and the stupid. Every advance in scientific medicine enhances the claim of our science and art to the reverence of those who undertake their study. When medicine was regarded and used as a mystery or a charm, and when its representatives were incapable of appealing to the intelligence of their age or were themselves half conscious of the hollowness of the system or systems which they practised, there may have been excuses for levity and insincerity in its votaries. But such times have gone for ever. Every step in the development of modern medicine as a science appeals to the interest and intelligence of the man who practises it as an art and adds immensely to his responsibility. Those who talk so glibly of the want of reverence in scientific men, and especially in medical men, are misinformed. We should be willing to have the truth of this view tested by the case of our medical students. We believe that even at an early and irresponsible age they are impressed powerfully and advantageously with the spirit of their profession They recognise that it calls for the highest qualities, mental and ethical, from its members and tends to develop those qualities. They note that the half-hearted student, and even the half-hearted lecturer, make no practical headway, and alike on high moral grounds and grounds of self-interest they take themselves seriously.

The matter and tone of the addresses which have ushered in the winter session at our medical schools will consequently appeal to many thoughtful young men. How could a young man upon the threshold of his medical career start better than the new students at Charing Cross Hospital have done by listening to Lord LISTER as he described his early researches leading up to the antiseptic system? A student entering on the study of medicine cannot expect to make for himself an everlasting name by such life-long studies of deep vital processes as those which have culminated in that antiseptic system which saves thousands of lives every day and has transformed our hospitals from veritable pesthouses to temples of healing, but every student can study the methods by which such success has been attained, and it can do him nothing but good to hope that his own work will be similarly beneficial to his race. He can imitate in a degree the spirit and the devotion with which these methods have been used and he can so acquaint himself with the facts and principles of the system as to ensure that in four or five years he will go forth into the world as a veritable saver of life, to be blessed by his generation wherever he goes. Another address should equally stir the student to be proud of the career of his choice, for it shows how world-wide is the bearing of the study of medicine. We refer to the address of Sir WILLIAM MACGREGOR, K.C.M.G., Lieutenant-Governor of British New Guinea, on Some Problems of Tropical Medicine, delivered at the London School of Tropical Medicine. Sir WILLIAM MACGREGOR modestly spoke of his technical ignorance of some parts of the subjects upon which he touched and excused himself as being an Administrator rather than a Doctor of Medicine. But his address, which we publish this week, is one which no mere Administrator could have written and which no physician could have excelled for the range of its medical knowledge and for the human and almost religious sympathy of its spirit. There is in it, too, that quality of the statesman which should inspire all medical men, especially those who deal with inferior races or classes. Sir WILLIAM MACGREGOR'S tribute to Mr. CHAMBERLAIN, and to the enormous service which as Secretary of State for the Colonies he has rendered to tropical medicine and through it to all tropical races, will be generally appreciated by the profession and even by the public. It is only a part of that larger service of high statesmanship which he has done for the colonies and which has thrilled them with new impulses of life and feeling towards the mother country. Even those who differ most directly from Mr. CHAMBERLAIN in general politics should forget their differences while they admit that he has done his best for races yet incapable of dealing with their own problems of disease. It will be well if both students and practitioners catch the enthusiasm, expressed in every line of Sir WILLIAM MACGREGOR'S address, for the possible results in the as yet untrodden fields of tropical medicine. "The man," he says, "who will work out an effective and practical means of dealing with contagious dysentery will be the greatest benefactor of the races that live in the tropics. He may claim to be the saviour of the Pacific Islander, the most loveable man of men now living."

We have left ourselves no space to speak of other addresses in detail, but our readers have had opportunities of reading last week in THE LANCET the words of Dr. G VIVIAN POORE, of Mr. H STANSFIELD COLLIER of Miss L. B. ALDRICH-BLAKE, M.D , and of Professor MCFADYEAN, and this week they will read with equal pleasure those of Sir JOHN WILLIAMS. In these addresses the absolute necessity of hard work, accurate observation, and systematic attention are duly insisted upon, but all the speakers have succeeded in holding up to their audiences a picture of the medical life which shows it to have great intellectual rewards but to offer no inducements to the man who is not earnest and self-sacrificing.

THE October issue of the *International Journal of Ethics* contains a highly interesting paper by Mr. R. BRUDENELL CARTER upon the difficult subject of Medical Ethics. Mr. CARTER has many qualifications fitting him to write with authority upon the theme. He has had in his professional life first-hand experience of general practice, of hospital practice, and of consulting practice, while ophthalmic surgery, which has in him so widely known an exponent, is both a pure specialism and intimately connected with all sides of medicine whatsoever. Moreover, Mr. CARTER was for many years an active member of the General Medical Council and has proved himself there and in other and more public arenas a logical thinker, an acute writer, and a fearless debater. It is not surprising, therefore, that what he has to say upon medical ethics is thoroughly worth reading, and we recommend a perusal of his article to all members of the medical profession, even while he is not in sympathy with movements which we know to make for progress. Ethical questions have a practical importance which has always been inherent in them but to which the immediate conditions of daily life have given unusual prominence, and it is absolutely necessary that the medical profession as a whole should strive to know what are the principles and rules by which professional conduct should be regulated. Undoubtedly the Ten Commandments inculcate the principles and include the rules, but the breadth of the precepts laid down in the Decalogue makes it occasionally difficult in a work-a-day world to decide what exact course should be pursued in concrete circumstances. We may know what is our duty towards our neighbour, but inasmuch as all mankind, and in a very special manner, is the neighbour of the medical man, it may well happen that we cannot see at once what is the line of conduct to follow where one neighbour must be preferred to another That many medical men experience this difficulty is particularly well known to us who receive daily requests to express an opinion upon the correctness or advisability of acting in certain ways in certain positions. We observe, by the way, that Mr. CARTER doubts the efficacy of this course because, to use his own words, "there is no evidence that the occupancy of the editorial chair has been preceded by any special study of ethical problems.' We would remind him—though, as he is obviously writing as an ethical expert, he should not require to have the fact pointed out to him—that in every walk of life to some extent a man learns his business by the carrying on of that business. It follows that, however unskilled Mr. CARTER'S imaginary editor may have been at the outset of his medico-editorial career in the theories of ethical lore, when he has sat for ten minutes in the editorial chair he will have begun to obtain an insight into the life of his professional brethren which cannot fail to make of him a very special student of ethical problems. And the editors of important journals, to which alone Mr. CARTER is referring, are not selected without an eye to their qualifications for office. We trust that these remarks will not be considered egotistical; they amount not to any claim of infallibility for ourselves, but only to an indication that we enjoy exceptional opportunities of understanding the difficulties of the medical life.

Medical ethics embrace two sets of questions—questions which relate to the conduct of medical practitioners towards the public and questions which relate to the conduct of medical practitioners towards each other. As Mr CARTER rightly says, there can scarcely ever be any real incompatibility between the duties which a medical practitioner owes to the public and those which he owes to his calling. And we think that the medical profession as a whole recognise this and do not discriminate between the two classes of questions in any way whatever. Prominence is more often given in medical journals to issues arising between two members of the medical profession than to those arising between medical men and the public, but this is because the columns of a medical journal form a natural place for the discussion of purely medical points, while matters in which the weal of the general public is concerned are better threshed out in the less domestic sheets of the lay press. But whether the debates upon medical ethics are conducted in the medical press or in the lay press, the wisest counsels are always given by those who remember that what is best for the medical profession is best for the public. An efficient code of medical ethics is that code which inculcates principles for the guidance of medical men which, if they follow them, will result in good to the public. The difficult point is how precise should those principles be made—when, that is, should the principles be defined by particular rules. It is obvious that it is not for the good of the community for a medical man either to treat a patient in association with a quack, or to throw the ægis of his professional position over a quack, and thus to enable him to practise an art in which he has not been duly instructed. A medical man must not consult with bone setters or herbalists or allow unqualified persons to visit and treat the public medically in his name, because by such misdoings the public would be gulled into purchasing as medical services the ignorant ministrations of the charlatan. It is easy here to turn the general principle into a particular rule But the translation may not be so simple and obvious. A medical man holding certain club appointments which place him in the position of the paid servant of laymen who demand from him work which he cannot do for remuneration which does not remunerate him, is not working for the public good. In many instances he is over-worked because the persons who avail themselves of his services are persons who really ought to pay for other medical assistance. In some instances he is underpaid because the lay managers of the association employing him desire to show a pecuniary balance, and can only do this by cutting down such immaterial expenses as the drug bill and the medical officer's salary. What rule, if any, is to be made about the men who fill these posts, for clearly they cannot be regarded in the category of those who regard quackery with complacency? Mr. CARTER gives no advice to the members of his profession upon this crucial point. He states the position and contents himself with adding that the General Medical Council cannot possibly treat members of the profession who choose to undersell their professional services as persons guilty of infamous conduct in a professional sense. We agree with Mr. CARTER here, but we cannot acquiesce in the view (which may or may not be his view, but which is held by many respectable persons) that nothing need be done. The principles of medical ethics are being violated and it is the proper part of the medical profession to make an organised attempt towards preventing the spread of the evil.

There is no longer any doubt in the minds of those members of the medical profession who have given ethical matters a share of their attention that the great weapon against abuses in any locality is solidarity of medical opinion. The series of articles which have appeared in our columns under the titles of "The Battle of the Clubs" and "Hospital Abuse," while proving that certain evils are widespread, have also shown that in many localities organised opposition to the exploiting of the medical profession has led to an abatement of abuse. This fact should encourage medical men in other districts to meet and to agree upon a definite line of action in regard to medical aid associations, while they should put completely out of their minds the idea that in forming and supporting such combinations they are exhibiting evidence of decadence from the standards of proper professional behaviour. It is the clear duty of medical men, upon the soundest ethical grounds, to take all measures to obtain for the public adequate medical service. Cheap medical work done by contract for lay employers, being without its proper professional stimulus, tends to become bad medical work; and to suffer bad medical work must always be contrary to medical ethics. This is the view which the medical profession should strive to educate the public to understand. They will not find it easy while some of their professional brethren can be found to stigmatise all attempts at the formation of professional opinion as mere combinations to raise prices, but they must not relax their efforts. From the constitution of modern society it follows that the principles of medical ethics cannot always be stated in rules, but the medical profession is doing its duty when it orders its conduct strictly towards providing the public with the best medical service.

UNIVERSITY COLLEGE, BRISTOL.- The introductory address in connexion with the Faculty of Medicine of University College, Bristol, was delivered on Oct 1st by Professor Stanton of the Engineering Department. The lecture dealt with the relative economy of the power derived from animals, food, coal, and other sources.

Annotations.

"Ne quid nimis"

ANEURYSM OF THE RENAL ARTERY

AMONG the rarest forms of aneurysm may certainly be classed aneurysms of the renal artery, for in an elaborate and interesting paper on this subject published in THE LANCET of Oct 6th (p 1002) Mr Henry Morris tells us that he has been able to find only 21 recorded instances in the whole of medical literature In two of these no particulars were obtainable, and of the 19 remaining cases 12 arose from injury and seven were spontaneous in origin, and from these figures it is seen that injury is the cause in nearly two-thirds of the cases Of the seven spontaneous aneurysms four were found at the necropsy and appeared to have given rise to few or no symptoms during life, in two others a tumour causing pain was noticeable, and the last case is remarkable seeing that in it the tumour and the kidney were successfully removed by Professor W W Keen of Philadelphia In the traumatic cases the most common form of injury appears to have been a fall The earliest traumatic aneurysm of the renal artery on record is related by Nebel who describes the case of a medical man He fell from his horse and four years later, in 1717, he developed a pulsating tumour in the left side of the abdomen and he died from the aneurysm bursting into the peritoneal cavity Curiously Titius describes in 1798 a very similar case, also of a medical man, who fell from his horse and died four years later from an aneurysm of his left renal artery It is perfectly possible that these were two distinct cases, but the coincidences are so many and so striking that we are justified in concluding that we have two separate accounts of one case As might be expected, the traumatic cases show a great preponderance in frequency in the male—two cases out of the 12 The age of the youngest patient was 15 years and of the oldest 66 years In many of the cases a "false" aneurysm was present—that is to say, an aneurysm no part of the wall of which was formed by the wall of the artery This false aneurysm may be formed in one of three ways It may result from the giving way of a small "true" aneurysm, which may have been of spontaneous or traumatic origin, or it may result from the yielding of a thrombus which has temporarily closed a ruptured artery; or, in the third place, it may be formed by the immediate outpouring of blood from a ruptured renal artery In the case under his own care which Mr Morris has contributed to the series the aneurysm followed immediately on the wound of the artery, and when operated on it was found to contain "several pounds' weight of blood clot" The diagnosis in these cases is often extremely difficult, for in most of them the two chief signs of an aneurysm, pulsation and bruit, are absent The history of an injury will be of but little assistance, for malignant growths are apt to follow injury, and hydronephrosis also may be traumatic in origin In the absence of pulsation the diagnosis may remain uncertain until an exploratory incision has been made The prognosis is extremely grave Every case that was not operated upon died Of the four cases in which an operation was performed three recovered, two of these successful cases were traumatic in origin, and the third was the spontaneous false aneurysm, under the care of Professor Keen, which has already been mentioned The records of these cases speak clearly as to the treatment to be followed The only chance of saving the patient's life is to perform excision of the kidney, with removal of the aneurysmal swelling If pulsation be present this may be decided on before the operation is commenced, but more commonly it will only be after an exploratory incision that the diagnosis will be made The dangers from hæmorrhage and from shock render the operation distinctly formidable, but the risk to the patient will be less than if the aneurysm be allowed to enlarge Mr Henry Morris's paper is a valuable contribution to the elucidation of an obscure subject

THE "LIMANKUR" IN ODESSA

THE term "liman" has been applied to the deposits of mud found at the mouths of rivers, but we here use it to denote an inland sheet of salt water formed by the silting up of the outlet of what was once an arm of the sea at the place where a river falls into it Odessa possesses three of these unusual features of the landscape called respectively Kujalnitzkiliman, Chadjebeiskiliman, and the liman of Liebenthal, of which the two former are the most important from a medical point of view The Kujalnitzkiliman is rather more than five miles from Odessa, is more than 18½ miles long, and is from one and a half to two miles broad, its depth is from six and a half feet to 16½ feet The "porosyp," or embankment of sand and mud, between the liman and the Black Sea is about a mile and a quarter broad The Chadjebeiskiliman is four and a half miles from Odessa, is 20 miles long, one and a half miles broad, and has an average depth of from 20 inches to 13 feet Evaporation has had the effect of making the liman water much denser than sea water, but its level and concentration are affected by rainfall and snow Analyses of the water of the Kujalnitzkiliman made in 1870, 1872 and 1894 show some extraordinary variations The last of these gave the total solid residue as 79 8 parts per 1000 and the sodium chloride as 58 0 parts per 1000 Analysis of the water of the Chadjebeiskiliman made in 1896 gave the total solid residue as 63 5 parts per 1000 and the sodium chloride as 48 1 parts per 1000 The total solid residue of the water of the Black Sea in the Bay of Odessa was found in 1894 to be 16 8 parts per 1000 and the sodium chloride to be 13 0 parts per 1000 The average temperature of the liman water from June to August may be put at 18 6° R (74° F), the average summer temperature of the air being 72° F Both animal life and plant life are well represented in a liman At the bottom of the water there is abundance of black mud of organic origin having an alkaline reaction and smelling strongly of sulphuretted hydrogen In 1892 new baths belonging to the municipality of Odessa were opened on Kujalnitzkiliman at a place about five and a half miles from the city and accessible by a railway The site has an area of 53,000 square metres (13 acres) and the buildings which are on the pavilion system, are divided into two sections for brine baths and mud baths, first and second class of each, with separate departments for each sex Patients may bathe in the open liman for from five to 20 minutes once a day, or twice with at least five hours' interval They may also have artificially warmed baths of the same water Mud baths may be had, the mud being either warmed naturally by the sun's rays or artificially by steam or hot water, the temperature of these baths is from 28° to 33° R (from 95° to 106° F), and the duration from 10 to 30 minutes, the mud bath is followed by a cleansing bath in fresh water, after which the patient goes to bed and assists perspiration by drinking hot tea, generally in astonishing quantities Sand baths are also given in the sand surrounding the liman The patient lies motionless in the sand either in the open or else in long boxes (Wannen) under a layer of sand four centimetres (one and a half inches) in depth, and they remain exposed to the sun's rays for from half an hour to an hour with a screen to protect their heads from the sun The "limankur" is indicated in rheumatism, rickets, the results of traumatic inflammatory processes (i.e., callus, ankyloses, and contractures), chronic joint diseases, osteitis, periostitis, myositis, pareses, neuralgias, chronic diseases of the skin, and late forms of syphilis. The treatment is contra-indicated in febrile diseases, heart diseases, arterio-sclerosis, amyloid degeneration, severe cerebral disease, epilepsy, pulmonary tuberculosis and new growths. With due precaution the baths may be taken up to the commencement of the second half of pregnancy. The natural features of these health-resorts and the methods of treatment followed there have been fully described in the *Deutsche Medicinirche Woohenschrift*, first by Stabsarzt Dr. Wilke of Dresden in 1897, and recently by Professor Adolf Baginsky of Berlin.

THE MEDICAL SOCIETY OF LONDON.

A MEETING of this society was held on Oct. 8th, the chair being occupied at first by Dr. Frederick Roberts and subsequently by Mr. John H. Morgan, the out-going and in-coming presidents respectively. The treasurer, Mr. D. H. Goodsall, presented his annual report. The subscriptions amounted to £508 14*s*. 6*d*., and though they were quite up to the average there had been no increase. The receipts included subscriptions from Fellows towards a magic-lantern, £16 4*s*. 6*d*., but this was not sufficient to purchase the instrument. The expenditure was about the same as last year and there remained a balance of £300, by which the whole of the debentures would be redeemed. Mr. H. Willmott Evans proposed, and Mr. John H. Morgan seconded, the adoption of the treasurer's report and a vote of thanks to that officer. Dr. George Shuttleworth proposed, and Mr. J. Peeke Richards seconded, a vote of thanks to the retiring officers and councillors. Mr. John Harold proposed a vote of thanks to the retiring President, Dr. Frederick Roberts, and this was seconded by Mr. Carter Braine. Dr. Roberts responded and conducted Mr. John H. Morgan, the in-coming President, to the chair. Mr. Morgan then delivered an address on the Romance of Surgery, which is published in full at p. 1061.

LUNG DISEASE IN THE NAVY.

A LETTER which appeared in the *Times* of August 16th, signed "Ernest Rason, retired Captain, Royal Navy," and headed "Lung Disease in the Navy," has aroused a good deal of interest and elicited a considerable amount of correspondence. Captain Rason quoted some figures which at first sight would certainly tend to show that lung disease in the navy has considerably increased during recent years. His figures show that "whilst the total of general disease has decreased one-fifth, diseases of respiratory organs have increased nearly one-fourth, that the increase of cases on the home station of diseases of respiratory organs has increased 60 per cent., and whilst the invaliding has more than doubled since 1883 from this complaint the general total of invaliding on home stations has considerably decreased." These conclusions are certainly disturbing to those who have the interests of the navy at heart, but when the figures are more closely examined certain fallacies are discovered. In the first place, Captain Rason was unfortunate in the years he selected for comparison—viz., 1868, 1883, and 1898. The above conclusions are fallacious, as the official statistics were after 1886 calculated on quite a different basis to previous years. Again, the term "diseases of the lungs" is very indefinite; in 1883 tuberculous disease of the lungs was not included under "diseases of the lungs" but under the heading "tubercle"; hence the inclusion of cases of pulmonary tuberculosis in later years under "diseases of the lungs" would make a vast difference in the statistics. In 1883 there was no influenza epidemic but in 1898 such an occurrence was the occasion of a very large number of cases being included under "diseases of the respiratory system," thus again detracting from the value of Captain Rason's figures. With reference to tuberculous diseases, mainly of the lungs, in 1883 there were 4·08 cases per 1000 in 1898 only 2·68—that is, of the total force; whils on the home station in 1883 there were 4·09 per 1000 and in 1898 2·49 per 1000, thus showing that tuberculou disease has actually decreased. Further, the statistic of 1868 show a considerably higher ratio of invaliding than those of 1898. The fears to which Captain Rason's statistics would give rise are therefore groundless. The correspondence by which this letter was followed is o interest as drawing attention to the different mode o life which is now experienced in the Navy as compared with the time when wooden sailing ships were employed In the steel steamships the men are certainly not so much in the open air as formerly, and if there be any increase in the number of diseases of the respiratory system this is probably the main cause. The suggestion that diseases o the respiratory organs are contracted in the training ship would appear to be improbable as the greatest attention is paid to prevent overcrowding and to promote efficiency o ventilation.

THE PROPOSED MEETING IN LONDON IN 1902 OF THE INTERNATIONAL CONGRESS OF GYNÆCOLOGY AND OBSTETRICS.

OUR readers are aware[1] of the circumstances under which an International Congress of Gynæcology and Obstetrics wa proposed to be held in London in 1902. We are now requested by the Council of the British Gynæcologica Society to publish the following translation of a letter from Dr. Jacobs of Brussels, permanent secretary of the Congress to the secretary of the society:—

> Much honoured confrère,—I write in the name of th foundation members of our Congress to ask you to expres to the President and members of the British Gynæcologica Society our united thanks for the efforts you made with view of the next session of the Congress being held i London. We are convinced that the incidents which unde the influence of certain members of the Obstetrical Society recently occurred in England are alone responsible for th failure of those efforts and that otherwise the British Gynæ cological Society would have secured for the session next ensuing a brilliant success. On the other hand, when made aware of those incidents, the founders found it impossible t ask your society to continue the organisation for the Congress to meet next time in London.
>
> In thanking you for all you have done in our behalf w desire to inform you that it is our decided wish that at some future time the Congress may meet in London, and our hope that the eminent members of the medical profession in England who are interested in the progress of obstetric and gynæcology may become permanent members of ou International Society.
>
> Accept, &c., the assurance of my most profound esteem,
>
> (Signed) JACOBS.

We are glad to see by the letter that the foundation members of the International Congress of Gynæcology and Obstetrics have taken the sensible course of postponing any meeting of the Congress in London for some years. By that time we may well hope that the differences of opinion which threatened to mar the success of the Congress which it was proposed to hold in 1902 will have been forgotten and will not be allowed to jeopardise the success of any future meeting. As we urged in an annotation upon the subject in THE LANCET of July 7th of this year, we think that when the question of a meeting of the Congress being held in London is next mooted it will be best to carry out the arrangements quite irrespectively of any particular society. The leading obstetricians and gynæcologists of the United

---

[1] THE LANCET, May 12th (p. 1398) and 19th (p. 1466), 1900.

Kingdom do not owe their position to their connexion with any society and an invitation issued in their names by a general committee would carry much more weight than one issued by the council of the Obstetrical or Gynæcological Societies. In a matter of this kind the disagreements of individual societies should not be allowed to intervene. We feel sure that in a few years' time a meeting in this country of the International Congress of Gynæcology and Obstetrics, invited by a representative committee of the obstetricians and gynæcologists of Great Britain and Ireland, should not fail to be an unqualified success.

DRUNKENNESS IN RUSSIA.

WE have already informed our readers[1] that even in Russia the offence of drunkenness is coming to be regarded much more seriously by the law than has hitherto been the case. Both parties in the Royal Commission presided over by Lord Peel recommend that drunkenness *per se* in public should henceforth be considered an offence, but we scarcely venture to expect such rigorous enactments in this country as those which have been already brought into action in Russia. In accordance with these all persons found intoxicated in streets and public places will be sentenced to terms of imprisonment varying from three days to a fortnight. A repetition of the offence is punishable with three months' imprisonment. If the accused is remanded the time which he spends in prison whilst he is awaiting his trial is not to count in his favour. It is said that the effect of this law, if rigidly applied to all drunkards in the streets, will be to throw at least 10 per cent. of the population into gaol.

THE NEW LABORATORIES OF KING'S COLLEGE, LONDON.

THE new science laboratories of King's College, London, will be formally opened on Tuesday, Oct. 30th, at 5 P.M., by Lord Lister, P.R.S. The Lord Mayor and sheriffs will take part in the ceremony, and a great number of invitations have been sent to representatives of learned societies, City companies, and local governing bodies, as well as to members of the teaching staffs of other colleges and medical schools. King's College has long held a prominent position on account of the excellence of the teaching which is carried on within its walls. The popularity of the classes, especially of those attended by non-matriculated students, and the demands for further accommodation for original research have necessitated such an increase of space as to involve an entire re-arrangement of the existing laboratories. The council wisely decided to meet this need by providing new buildings, structural alterations, and new equipment which will cost over £20 000. An appeal was made to the public which, in spite of the demands for the various war funds, was generously, however inadequately, responded to. The new scheme was nevertheless carried out and a large debt has been incurred, but the College has at any rate the satisfaction of possessing laboratories for physiology, bacteriology, biology, botany, and geology which can compete with the best laboratories of the continental schools. The physiological laboratories are entirely new and form a magnificent suite of rooms consisting of a very large central laboratory fitted with all the requisite apparatus, a room for advanced classes, a laboratory for physiological chemistry, and a room for the professor. The bacteriological department, which since its foundation nearly 15 years ago has been the most complete of its kind attached to any medical school in England, has been considerably enlarged. There are a technical laboratory, a new class room, a research room, and a bacteriological library which we believe to be unique. There is also a new lecture theatre available for both bacteriology and physiology. In the same block there are also very fine rooms and laboratories to be devoted to teaching and research in geology and botany. The College museum has also been moved and the old museum has been reconstructed and fitted for the architectural department. The transference of the physiological department to the new buildings has enabled the anatomical department to obtain much-needed additions by absorbing the old physiological laboratories. There have also been great improvements made in the accommodation for teaching physics, pathology, materia medica, and state medicine as a result of the additions to the College premises. The new laboratories will be open for inspection after the ceremony and any member of the profession who has not received an invitation to be present may obtain one by applying to the secretary of the College.

ETIOLOGY OF PELLAGRA.

IN *Il Policlinico* of Sept. 1st Dr. Ferrati of Pavia records some observations which he has made on the symptoms produced by fungus-infected maize. In 1896 he and Dr. Gosio published in the *Rivista d'Igiene e Sanità Pubblica* researches showing (1) that the watery or alcoholic extract of maize containing hyphomycetes is very toxic for the common grey mouse (mus musculus), and (2) that the toxicity is due to, or associated with, a putrefaction simultaneously giving rise to products belonging to the aromatic series ("fermentazione aromatica"). Dr. Ferrati and Dr. Gosio used only the common mouse for their experiments, this animal being very sensitive to the toxins elaborated in maize. Dr. Pelizzi and Dr. Tirelli had, however, announced in 1894 that the putrefaction products of maize containing hyphomycetes were not toxic for rabbits or dogs, and with the object of testing this statement Dr. Ferrati continued his researches during 1897. Porridge ("polenta") made with good maize flour was cut into large thin slices which were sterilised in a current of steam at 100°C. for 30 minutes on three successive days. Having remained sterile for the next three days the porridge was treated with spores of penicillium glaucum suspended in sterilised water. The penicillium glaucum had been freshly isolated from maize, and when it was cultivated on Raulin's fluid there was an abundant production of phenols giving a red-violet colour with ferric chloride. In a few experiments common yellow bread or bread made with a mixture of maize and rye such as is sold in the shops in Pavia was submitted to the same process. The porridge or bread thus treated was left in the dark at the ordinary temperature for eight days and was then extracted with alcohol, the extract thus obtained being afterwards dissolved in water and administered to various animals either subcutaneously, intravenously, or mixed with their food. Except with mice all attempts to produce acute poisoning with the extract failed, but chronic poisoning could unquestionably be brought about in dogs, although not in rabbits. A dog weighing 5 lb. treated with subcutaneous injections of the extract on alternate days became in 16 days affected with general debility, drowsiness, and profuse diarrhœa and died 35 days later—namely, 51 days from the commencement of the experiment. A second dog weighing 12 lb. was fed plentifully with good bread, to which were added every day 150 grammes of the porridge or bread containing penicillium glaucum, boiled with sugar and water or milk. In 64 days it suffered from general debility, stiffness of the body and of the hind legs, dysphagia, and diarrhœa with blood in the fæces. 43 days later it was attacked with convulsions and the feeding with the fungus-infected maize was then finally abandoned. The convulsions ceased in about a week and the animal gained a little of the weight which it had lost, but it continued to suffer from stiffness of the back and spastic paresis of the hind quarters, and it died 173 days from the commencement of the experiment. Dr. Ferrati points out that the symptoms presented by this dog were almost identical with those produced in dogs fed on damaged maize ("mais guasto") gathered in the fields as described by C. Lombroso in 1891. In conclusion, he states at some length his reasons for supposing that pellagra is due to toxins produced in maize by moulds (hyphomycetes) and not to toxins produced by bacteria (schizomycetes).

[1] THE LANCET, July 14th, 1900, p. 121.

A POLICE-COURT REFORM.

THE law's delays are proverbial and the cost which these entail has often proved a highly inconvenient and an injurious reality. For this reason the London public will follow with more than ordinary interest the fate of a proposal which is now before the Home Secretary, and which aims at lightening the duties of metropolitan police magistrates by transferring a portion of their less important business to the hands of county justices. In the opinion of some the proposed arrangement will prove beneficial both by relieving a stress of work and by keeping out of a criminal court a relatively innocent class of cases such as those of non-attendance at school and others of miscellaneous character. Others, however, maintain that further legal efficiency is rather to be sought by adding to the number of metropolitan police magistrates. Whatever decision may finally be arrived at it is much to be desired that the result will be a quickening of the too slow movement of law in an urban police-court. Much, we trust, may be expected from a redistribution of business, but even this must partly fail of its object unless it is supplemented by the adoption of more business-like methods than those which now prevail. The summoning and hearing of witnesses in particular might well be carried out on some better system than that at present in use. It should at least have some relation to the date and hour at which their evidence is likely to be taken. We allow that the duration of the hearing of cases is uncertain, but even so it should be possible to arrange them in some sort of order so as to obviate the attendance of witnesses for several days before their services are required. Bail cases are commonly taken late in the sittings of the courts, yet we have known witnesses for such cases to be called for the earliest hour on the first day of the sittings. It is hardly necessary to point out how greatly a want of method such as this indicates must interfere with the conduct of ordinary business. Our own profession is a sufferer by this lack of order and it is not necessary to dwell on the possible consequences of a practitioner's uncertainty in cases of critical illness. The saving of court expenditure, moreover, wherever practicable, is a not unworthy object. By a little ordinary foresight and management it might in many cases be at least halved. For more reasons than one, therefore, it is to be hoped that the very moderate measure of reform which we have indicated will not be overlooked in the proposed adjustment of police-court business.

ASTHENIC BULBAR PARALYSIS.

DR. ARTHUR J. HALL of Sheffield records in the summer number of *Brain* an interesting case of asthenic bulbar paralysis, a rare disease and characterised by symptoms similar to those of a case under the care of Dr. Wharton Sinkler previously recorded in these columns.[1] The case is that of a married woman, aged 44 years, a multipara, a sufferer from migraine and descended of a long-lived but nervous stock. Two of her sisters have suffered from severe migraine and a third sister has melancholia. There is no personal history of syphilis. Recently she has suffered profuse and painful menstruation and has had two years of considerable domestic worry and anxiety. The present illness began in December, 1896, when she complained of general muscular weakness. "She always seemed tired and could not even hold a tea-cup for long at a time." On Christmas Day she developed ptosis on the left side, while a swelling appeared on the same side of the face. The weakness and ptosis gradually increased, and one day in February, 1897, she fell down apparently from excessive weakness. She was put to bed and complained of headache and said that "things appeared all out of shape." Slight ptosis then appeared on the right side. The ocular muscles acted irregularly and she lay in bed languid and depressed with extreme muscular prostration, being unable even to sit up. There was no muscular wasting or loss of sensation. Control over the sphincters was normal. The superficial and deep reflexes were normal and there was no ankle clonus. Speech was slow and droning and the voice was feeble and tired. The muscles of mastication were easily tired. Ophthalmoscopic examination showed no abnormality in the fundus of the eye and electrical reactions were perfectly normal. She was placed in a private nursing home and treatment according to Weir-Mitchell's method (overfeeding, isolation, electricity, and massage) was carried out under which she improved a little for a while. The diagnosis was doubtful. A menstrual period then came on which lasted 10 days, during which she menstruated profusely. She now became rapidly worse and extremely feeble and depressed. She had occasional attacks of dyspnœa and the circulation became feeble. On April 2nd she had some beef-tea after which she suddenly began to have dyspnœa, became cyanosed, and died in a state of collapse, the respirations being stertorous and the pulse 100, while urine was involuntarily passed before death. A post-mortem examination of the brain and medulla oblongata was made on April 5th and so far as could be distinguished by the naked eye the examination "revealed absolutely nothing in any part of the membranes, vessels, or nervous tissue which could be distinguished from that of a perfectly normal adult." Portions of the pons, medulla, cerebral and cerebellar cortex were hardened in Müller's fluid, cut in celloidin, and stained by Weigert's method, aniline blue-black and alum-carmine. "A careful examination of a large number of sections failed to reveal any changes in the nerve-cells or fibres or in the interstitial tissue or blood-vessels." The disease was thus known to be the rare nervous affection known as asthenic bulbar paralysis or myasthenia gravis, only 10 cases of which have been described in this country since Wilks first described it in the *Guy's Hospital Reports* for 1877.

THE EXPECTATION OF STATURE IN BOYS AT 13 YEARS OF AGE.

IN France boys of 13 years of age who are orphans or whose parents may be in necessitous circumstances are admitted into State schools with a view to their becoming soldiers. The course of instruction extends over five years, but during this period the pupils are not taught any profession or trade which would enable them to gain a living as civilians. At the age of 18 years they are admitted to the ranks, provided that their stature is sufficient, but should they fail to measure five feet (which is the minimum standard for a French foot-soldier) they are summarily rejected. Writing in the *Archives de Médecine et de Pharmacie Militaires* for August Surgeon-Major L. G. Godin proposes to save these young men from being thus "thrown literally on the pavement" by fixing a minimum height below which no candidate for admission to the Government military schools can be accepted. It is quite possible, he thinks, to predict the stature which a boy of 13 years of age will have attained to on the expiration of five years. According to authorities consulted by him the average increment during the lustrum in question is 20 centimetres, or nearly eight inches, but should this datum be adopted it would place the rejection height at 1·34 metres, which his experience teaches him is not sufficiently low. Of 1000 boys whose cases came under his personal observation seven measured 1·33 metres at the age of 13 years, 13 measured 1·32 metres, and six measured 1·31 metres. In the first category three boys attained to the regulation height in five years, in the second the number successful was also three, but in the third there was only one, the percentage of failure being respectively 58, 77, and 84. In conclusion Surgeon-Major Godin gives it as his opinion that all boys of 13 years of age who measure 1·34 metres and upwards may be freely accepted in the schools, but that in the cases of boys who are under this height the examining medical man should look for guidance to the attendant circumstances. If an undersized boy has been badly fed, presents no signs of puberty, and has parents of good stature, the chances are that he will grow sufficiently during his period of probation. To chest circumference and weight as indicators of future height Surgeon-Major Godin attaches little or no importance. The minimum height he would establish is 1·30 metres. 12 boys out of *the 1000 were of that stature or less when they were 13 years* old, but not one of them grew sufficiently during the next five years to enable him to pass the test.

[1] THE LANCET, Oct. 21st, 1899, p. 1110.

BACTERIAL LIGHT.

WE are indebted for a good many things to the wondrous synthetic and analytical powers of micro-organisms. Bacteria are being utilised in the arts and manufactures and they promise soon to be the effectual scavengers of the offensive products incidental to the existence of human life. Indeed, it would seem that the great species of bacteria around us present a variety of functions which doubtless could be turned to many a good account Bad microbes we know there are whose subtle operations set up the specific poison of disease, but it would indeed be a very odd circumstance if time should prove that the microbe can be so manipulated as to afford us artificial light. Yet there exists a microbe which when properly fed will grow and multiply enormously, emitting during its development a strange phosphorescent light. In the past we have been wont to look upon phosphorescence as a phenomenon due essentially to the presence of phosphorus somewhere. We now know that this is a mistake, for phosphorescence occurs in a very great number of instances in the entire absence of phosphorus. Phosphorescence is undoubtedly a manifestation of chemical or physical change, but the change, of course, may not always be due to the working of countless microscopic organisms. It certainly is in the case of the phosphorescence of the sea. In this case the phosphorescence is best when the sea is disturbed and the maximum of light is emitted from the crest of a short, rapid wave or in the foam produced by *some disturbance. This is due to the fact that the phos*phorescent bacteria or photo-bacteria are much more active in the presence of an excess of oxygen. Indeed, the respiratory exchange or oxidation of the bacteria is the cause of sea phosphorescence, since if the micro organisms be killed or oxygen be excluded the light is quenched at once, while on adding an abundant supply of combustible food-stuff such as sugar the light is intensified. The glow of ordinary yellow phosphorus is, of course, due to direct oxidation without the agency of micro-organisms. The peculiar greenish glow seen upon stale haddocks and other sea fishes is produced by this remarkable photo-bacterium and is in no way connected with the presence of phosphorus. It is possible to cultivate the phosphorescent bacteria so as to obtain a fluid which is very strongly phosphorescent. Thus by placing the flesh of fresh haddocks or herrings in a from 2 to 3 per cent. solution of common salt and keeping at a low temperature—about seven degrees above freezing—it will be found that after a few days, not merely the fishes, but also the whole of the liquid in which they are immersed, give off a pale greenish light which becomes much more brilliant if a little sugar be added. Pure cultures may thus be obtained exhibiting such a strongly phosphorescent light that by protracted exposure they may be photographed by their own light. It is not possible to say whether the culture will ever be carried to such a pitch that the vessel containing it may be used with advantage as a street lamp or a lamp upon our tables, or as a Chinese lantern at our garden-parties. But the wonderful functions of bacteria are many and the possibilities of using their powers multifarious.

EPSOM COLLEGE.

FOR some years past the boys in this school have done themselves no little credit in various public examinations and the work of the staff continues to yield excellent results. In the last five years the school has gained 12 open scholarships at the universities for classics, mathematics, history, and natural science. *One boy has passed direct into Woolwich* and passed out in the Royal Engineers. No less than 73 boys have passed the London Matriculation, 21 boys have passed the whole of the Preliminary Scientific Examination at one time direct from the senior modern form, and 21 others have also passed one part of the same examination. Three boys have passed the intermediate examination for the degree of B.Sc and two others have been successfully prepared for the first conjoint examination. Each summer several whole forms enter for the higher and lower certificates of the Joint Universities Board. 36 higher certificates (with four distinctions) and 144 lower have been won and in this period the total failures in these whole forms amount to 50 only. In making such a summary as this it is useful to turn to the doings of boys who have left the school. Amongst other distinctions gained we may notice a first and a second class in classical moderations at Oxford and a second in the classical tripos at Cambridge, three first classes and five second classes in the science tripos at Cambridge, besides honours in law and in history, the "Sword of Honour" at Sandhurst, a gold medal with honours in the final examination for the M.B Lond., and many other distinctions in various medical examinations. There is scarcely a hospital in London at which important posts have not recently been held, or are now held, by former members of the school, and those who have proved failures after leaving the school may be counted on the fingers of one hand The pupils of the college being drawn from all classes of society, a breadth of tone in the educational and school life pervades the whole school, with results much to the advantage of the students in their after life.

MISLEADING NEWSPAPER REPORTS.

A REMARKABLE paragraph recently appeared in one of the morning papers to the effect that the country is exposed to grave dangers from epidemics of enteric fever originating from the return of invalided soldiers from South Africa. An outbreak of enteric fever occurred in a village, and according to the newspaper report the medical officer of health of the district stated that upon investigation he attributed the outbreak to a member of the Imperial Yeomanry who had returned home invalided from the front in August. He had been inoculated against enteric fever and on his return was allowed by the military authorities to proceed home instead of going to Netley Hospital.

Two days afterwards a relative became ill and numerous other cases of enteric fever subsequently occurred in the village. The report adds: "The medical officer thought that the attention of the Government should be called to the case, as if patients of this sort were allowed to return direct to their homes there was a great danger of a general epidemic in the country." There are obvious absurdities in the above report, such as the idea that a person who has been "inoculated" against enteric fever could convey the disease to another, or that enteric fever could appear only two days after the supposed exposure to infection. We communicated with the medical officer referred to and received a reply from him showing how inaccurate the report was. The member of the Imperial Yeomanry referred to was inoculated with the serum for prevention of enteric fever on the voyage out to South Africa, but nevertheless suffered from an attack of the fever in May and was invalided home in August, and he was two or three weeks in his father's house before other people were attacked. We do not think that it has at all been proved that the outbreak of enteric fever in the village referred to can be traced to the home-coming of this member of the Imperial Yeomanry. Our knowledge of the length of time during which a patient may remain a source of infection after certain fevers is not definite, but it would seem to be very improbable that if the patient had been attacked with enteric fever and had been invalided home in August (unless, indeed, the disease had been prolonged by relapses) he could then have been the means of conveying infection to others. Every care will, of course, be taken with soldiers returning home from South Africa to prevent them becoming sources of infection, but the time allowed for convalescence is in nearly all the cases considerably longer than that allowed for patients who have been treated in English hospitals, and there is no cause for fear that the return of our soldiers is likely to prove a source of danger to their friends or to the community at large.

THE DEW-PONDS ON THE DOWNS.

The formation of dew-ponds on the downs, notably on the South Downs, has given rise to some very interesting speculation. Some of the ponds are of such size that it is a matter for wonder that the large bulk of water contained in them is maintained in spite of the enormous evaporation that must go on. There is a factor somewhere which must compensate for this rapid evaporation in such an exposed position for in dry weather or drought the dew pond remains full while the ponds in the valleys are empty. This factor, whatever it may be, is an important one, since without it the supplies of water for the sheep on the hills would probably soon cease. There is some contention as to the probable explanation of the supply of water being thus kept up. Recently, however, some experiments have been made of a quite simple character which, so far as they go, indicate how it is that water is almost always found in these high elevated hollows. The source of water at any rate is not a geological one. It is thought that a difference of electric potential must cause an attraction between the particles of moisture and the summit of the hill upon which the pond is situated. A simple experiment would seem to confirm this view. Thus by placing two similar receptacles in the neighbourhood of a dew-pond it was found that there was a marked increase in the water collected in the basin which was connected to the earth by means of a conductor, while in the insulated basin the quantity collected was decidedly less. Although this simple but extremely interesting experiment was necessarily imperfect owing to the difficulty of completely insulating a vessel under an environment of moisture, yet the indication seems clear. Whether or not by a perfect system of "earthing" reservoirs the quantity of water in the dew-ponds could be increased is a very interesting possibility to ponder over. Possibly if good results were obtained by this method we might derive a new, as it certainly would be a remarkable, source of supply of water for drinking purposes. The water so obtained would of course be pure and practically identical with distilled water.

LEONTIASIS OSSEA.

In the September number of the *Medical Chronicle* Mr. W. H. Stephenson of Harpurhey, Manchester, describes a case of the rare disease leontiasis ossea. The patient was a man 27 years of age. When 13 years of age he noticed for the first time a slight hard painless swelling on the left side of the lower jaw which had been gradually increasing in size ever since. About 18 months ago a similar swelling had commenced on the right side of the lower jaw and had gradually increased in size,. but was not accompanied by any marked pain. During the last 12 months he had noticed that the bones of his nose had been growing larger and that the nose had become markedly increased both in thickness and breadth—the left side rather more than the right; the left nostril had become almost occluded. During the last two months he had suffered at various times from severe neuralgic pains in the lower jaw especially on the left side, the pain extending up the left side of his face almost to the temple. Otherwise he enjoyed good health and was able to follow his usual employment His family history appeared to be very good. Mr. Stephenson found the whole of the lower jaw thickened and hypertrophied, especially the left half, and on examining the interior of the mouth the broadening and thickening of the alveolar margin were seen to be well marked. The teeth appeared to be somewhat small. The nasal bones were considerably enlarged and the left nostril was almost occluded. The superior maxillæ were slightly enlarged and there was a distinct bulging of the left frontal eminence. All the other bones appeared to be normal except that the patient suffered from slight genu valgum of the right leg. Two portraits which accompany the paper show a man of an intelligent aspect, with regular features free from disfigurement, although the fulness at the angles of the jaw is sufficiently noticeable. Leontiasis ossea was first described by Virchow and subsequently by the late Sir James Paget It is a hyperostosis distinguished from acromegaly by being confined to the facial or cranial bones.

THE QUESTION OF THE COMMUNION CUP.

In another column will be found a letter from a correspondent referring to the danger of infection which exists owing to the use of a common chalice at the administration of the Holy Sacrament. The point which our correspondent brings forward is a very real one and one, moreover, which should be taken up by ecclesiastical authorities without delay. We have ourselves commented upon the question on many previous occasions, to give an instance in our issue of Feb. 1st, 1896. There are three methods by which this danger may be avoided, but only two need be seriously considered. These are, one, the Roman Catholic mode of communion of the laity in one kind only, and the other the method of communicating technically known as "intinction"—namely, the bread being dipped in the wine. This latter method is still used in the Eastern Church and was common throughout the West up to the twelfth century. It went through various vicissitudes, being now allowed by one council and now forbidden by another, until at length, with a view of bringing about uniformity, the chalice was forbidden to the laity. The third method, mentioned by our correspondent, of a separate glass or cup for every communicant, is quite modern, has never so far as we know been adopted by any branch of the Church, and to our minds is open to the charge of introducing complications into a rite which should, at every cost be kept dignified, solemn, and reverent in its ritual, however much or little of this last there may be. Into the theological arguments for or against "intinction" or those which led to the supersession of the latter by communion in one kind only we shall not enter, for it is not our province to do so. But we earnestly urge the ecclesiastical authorities of the Church of this land to consider the matter. The Church in former days was a leader in sanitation, witness the way in which the great religious houses drained fens, planted waste places, and taught men the advantage of living a regular life under a disciplined rule. It is none the less her duty now to remove occasions of stumbling.

THE SIGNIFICANCE OF CHANGES IN THE CEREBRAL GANGLION CELLS IN PSYCHOSES.

IN the *Berliner Klinische Wochenschrift*, No. 32, 1900, Dr. E. Meyer gives an account of his studies based on cases at the psychiatric clinic of the University of Tübingen and made with a view to determine the significance of the cortical changes in the cerebral ganglion cells in acute mental diseases. The examination of microscopic specimens prepared by Nissl's and other methods showed interesting changes, the cases studied being one of delirium tremens in a woman aged 41 years, one of septic delirium and typhoid fever with high temperature, two of insanity following renal disease and uræmia, two of delirium associated with the inanition of pulmonary phthisis, one of acute delirium in a young woman aged 22 years, one of delusions of persecution in a woman aged 59 years, one of melancholia terminating in delirium acutum, one of mental confusion passing on to katatonia, and one of hallucinatory delirium occurring at the climacteric period. Many changes especially of a chromatolytic character as regards Nissl's granules were found, affecting especially the large and "giant" pyramidal cells, the extent and distribution of the changes being variable. Cases with septicæmic complications—e.g., multiple abscesses, purulent nephritis, and enteric fever—showed changes similar to those without such complications, though in the latter cases the agency of toxic substances—e.g., alcohol—could not be excluded. Dr. Meyer thinks that not all psychoses are accompanied by change in the ganglion cells, while those changes found to be present are known to occur in entirely different diseases marked by differences of etiology and clinical history, and hence that such changes are not pathognomonic. Many of the cellular changes (chromatolysis, fatty and pigmentary degenerations) are common to several and different psychoses, although the distribution of these changes in the various cortical "areas" may be different.

THE UNIVERSITY OF LONDON.

AS we announced in our issue of Oct. 6th was to be the case a meeting of the Convocation of the University of London took place on Oct. 9th for the purpose of electing members to serve on the Senate under the statutes made by the Commissioners. Mr. H. E. Busk, the chairman of Convocation, presided and before the business of the election commenced a motion was adopted expressive of the sympathy of the University with Her Most Gracious Majesty the Queen upon the occasion of the death of the Duke of Saxe-Coburg and Gotha. Polling then commenced and continued for some three hours. Members were elected by the registered graduates in Science, Arts, and Medicine and Surgery respectively. The graduates in medicine elected Dr. Thomas Barlow with 381 votes and Dr. Joseph Frank Payne with 314 votes, as against Dr. Sydney Ringer with 243 votes and Mr. Quarry Silcock with 212 votes. We are sincerely glad at this result, for, as we said last week, Dr. Barlow and Dr. Payne are in accord with the views which we hold upon the question of the establishment of a real teaching university for London, while Dr. Ringer and Mr. Quarry Silcock favour the continuance of the *status quo*. The Faculty of Medicine of the University will this afternoon (Friday), at 4 P.M., hold their first meeting at South Kensington for the purpose of electing three representatives upon the Senate in accordance with the new statutes. The three Senators elected by the Faculty will be *ex officio* members of the Academic Council, one of the most important standing committees of the Senate in its re-constituted form. With so small a number to elect probably no attempt will be made to choose candidates merely as delegates of particular medical schools, nor does it seem desirable that the Faculty should go outside its own body to find representatives. We understand that the following candidates will be put forward: Dr. J. Kingston Fowler, Dr. E. C. Perry, Dr. H. Montague Murray, Mr. A. A. Bowlby, and Dr. Isambard Owen, and doubtless other names will be submitted to the Faculty It was at one time thought that at this meeting a Dean of the Faculty would be elected, and Mr. H. T. Butlin's name has been mentioned in connexion with this important post. At the last moment, however, it has been ascertained that the election of dean must be postponed until the new Senate has prescribed the manner of election.

UP to the time of going to press the following medical candidates have been re-elected Members of Parliament:—R. Ambrose, L R C P. & S. Edin. (Mayo West); John Dillon, L.R.C S Irel. (Mayo East); R. Farquharson, M.D. Edin. (Aberdeenshire); Sir B W. Foster, M.D. Erlang., F.R.C.P Lond. (Derbyshire, Ilkeston); M. A. MacDonnell, M.D. R.U.I. (Queen's Co., Leix); Sir M. Foster, M.D. Lond., K.C.B. (London University); C. K. D. Tanner, M.D., M.Ch. R.U.I. (Mid Cork); and Sir J. Batty Tuke, M.D. Edin. (Edinburgh and St Andrews Universities). The following new Member has also been elected:—F. Rutherford Harris, L.R.C.S Edin. (Monmouth District). Sir R. B. Finlay, the Attorney-General, who was at one time a medical practitioner, has also been re-elected.

THE death is announced as having occurred on Saturday last, Oct. 6th, of Mr. John Frederick France, F.R.C.S. Eng., Mr. France, who retired from the medical profession some years ago, received his medical education at Guy's Hospital, where he was at one time ophthalmic surgeon and lecturer on ophthalmic surgery He edited "Morgan on Diseases of the Eye." He was a Fellow of the Society of Antiquaries and a justice of the peace for Middlesex.

THE opening meeting of the next session of the Chelsea Clinical Society will be held in the Holy Trinity Parish Hall, Pavilion-road, Sloane-square, on Tuesday, Oct. 16th, at 8.30 P.M. An address will be delivered by the President, Dr. William Ewart, on a Clinical View of some of the Mechanisms of the Heart and its Valves This meeting will be open to all members of the medical profession on presentation of card.

PROFESSOR B. C. A WINDLE, Dean of the Medical Faculty of the University of Birmingham, has been nominated by the Council to represent the newly established University on the General Medical Council.

A NEW out-patient department for mental disorders has been opened at Charing-cross Hospital and Dr. Percy Smith has been appointed physician-in-charge. Patients have to attend on Wednesdays at 9 30 A.M.

A FEW WORDS ON THE PUBLIC HEALTH SERVICE.

AT the meeting of the West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health, held in Bristol on Oct. 4th, the presidential address was delivered by Mr. J. Herbert Jones, medical officer of health of the Rhondda urban district. After some preliminary observations on the existing administration of the Public Health Acts in England and Wales, and a disclaimer of any intention to suggest a scheme for reform of the public health service, Mr. H. Jones proceeded to give a *résumé* of the manner in which certain Acts of Parliament akin to the Public Health Acts were carried out, his opinion being that a study of the particular methods adopted in other public departments might be useful to the members of the society. He said:—

"The particular statutory enactments with which I will concern myself are the Factory Acts, the Mines Regulation Acts, and the Education Acts. The first two are administered by the Home Office—a department presided over by the Home Secretary, who is invariably a Cabinet Minister. The Education Acts are administered by local school authorities, but a controlling power is in the hands of the Board of Education—a department represented in Parliament by the Vice-Chairman of the Committee of Council, who does not always occupy a seat in the Cabinet. The practical administration of the Factory and Workshops Acts is in the hands of inspectors who are appointed to promote and enforce the uniform working of the Acts, the provisions of which are concerned with the safety of the workpeople, with the sanitary conditions of the places in which they work, and with the hours during which women and children are employed. There is a chief inspector who is responsible for the working of the department and for the carrying out of the Acts throughout the United Kingdom. He is stationed in London and has his headquarters at the Home Office. Then there are five superintending inspectors to whom are assigned definite 'divisions'; their headquarters are placed in large centres of population, such as London, Glasgow, Manchester, Birmingham, and Leeds. Each superintending inspector has under his supervision district inspectors, to whom are allotted definite areas within the wider division. These latter in large districts have the help of junior inspectors and assistants. There are altogether 47 inspectors attached to districts (15 ranking as first class and 32 as second class) and there are 37 junior inspectors and 31 assistants. In addition to the divisional and district staff the chief inspector has the further assistance of a deputy chief inspector, a medical inspector, an engineering adviser, an inspector of cotton cloth factories (and other factories in which artificial humidity is employed), and a principal lady inspector, under whose immediate direction are six lady inspectors. The inspectors are nominated and appointed by the Home Secretary after examination which is in part competitive in certain subjects. Their salaries are increased periodically up to a fixed maximum. An inspector may be called upon to retire at the age of 60 years and he is compulsorily retired at 65 years, in each case becoming entitled to superannuation. In exceptional circumstances he may be employed for a further term of five years after he has reached the age of 65 years.

The Coal Mines Regulation Acts of 1887 and 1896 contain provisions as to the employment of boys, girls, and women, the payment of wages, the prohibition of single shafts, the division of mines into parts, the appointment and certification of managers, inspection of mines, arbitration in disputes, as to coroners' inquests, the ventilation of mines, and as to general and special rules, &c. The Acts are enforced by officials of the Home Office styled inspectors of mines. Concerned with metalliferous mines alone there are one inspector and two assistant inspectors. For coal and metalliferous mines there are 12 inspectors and 24 assistant inspectors. To each inspector is allotted a district and he has associated with him assistant inspectors who in their turn have charge of a defined area The time of the inspector is primarily occupied in making inspections either at irregular intervals upon his own initiative, or when asked by some responsible person to do so, or when he receives a complaint of conditions calling for investigation. The inspectors possess extensive powers of entry to the works with which they are concerned and have very large powers enabling them speedily to enforce the provisions of the Mines Acts. They meet in conference in London once a year and oftener if necessary. The expenses of these meetings are defrayed by the Home Office. They are appointed by the Home Secretary and must have submitted themselves to examination in certain subjects relevant to their particular calling. They are paid a gradually increasing salary up to a maximum and are subject to the same regulations as to superannuation and retirement as factory inspectors.

The administration of the Factory and Workshops Acts and of the Mines Regulation Acts is entirely in the hands of the central authority. The Education Acts, on the other hand, more nearly resemble the Public Health Acts in that they are administered by local authorities controlled by a central authority. With the detailed work of the school boards or school committees I will not trouble you, but I will confine myself to the part played by the Board of Education. The duties of the local school authorities are set out in the Education Acts and in a code issued year by year by the Board of Education. The provisions of the code and of the Education Acts are to a certain extent enforced by a large staff of inspectors acting under the Board of Education. There are 12 chief inspectors, one of whom is designated senior chief inspector, and 91 inspectors. Then there is a staff of some 200 sub inspectors, one fourth of whom are styled first class and the remainder second-class sub-inspectors; these are usually drawn from the ranks of those teaching in the public elementary schools. Each of the 12 chief inspectors has allotted to him a division which is again subdivided into smaller areas under the control of an inspector who has associated with him one or more sub-inspectors. The inspector is not subordinate to the chief inspector, but reports to, and receives instructions directly from, the Board of Education. The sub-inspectors, on the other hand, report and take instructions through the inspector. The chief inspectors have periodical conferences with each other, and the chief inspector has conferences with the inspectors in his division in order to secure substantial uniformity of judgment and practice throughout a division. The expenses of these conferences are borne by the Board of Education.

In conclusion, I cannot refrain from asking you to contrast the administration of the Acts of Parliament which I have enumerated with the administration of the Public Health Acts as we know it in many parts of the country. There are, I admit, many towns and districts in which the local authority is alert and has a full sense of its great responsibilities, but this is the exception rather than the rule. Cannot something be done to make the exception the other way?"

THE WAR IN SOUTH AFRICA.

THERE is but little to be chronicled about the military situation in South Africa. As might have been confidently expected, now that the war has reached a final and merely guerilla stage, there have been much desultory fighting and occasional military raids on the part of the Boers. Their resistance as an organised body has been overcome and the back of the campaign is broken, and we are now witnessing the sequelæ of what has gone before. The Royal Commissioners having inspected all the hospitals and finished their work in South Africa, will soon be on their way to this country, where they will examine some more witnesses and complete their investigations. The publication of their report will, we need scarcely say, be awaited with great interest. Army reform will occupy a front seat in the immediate future and with Lord Roberts as the new Commander in-Chief—especially if supplemented and aided by the organising capacity of Lord Kitchener—the nation may expect to have the subject thoroughly threshed out. We can only trust that the danger will be avoided of perfecting a scheme which, however admirably adapted it may be for fighting the Boers under the exceptional conditions which obtained in the veldt and uplands of South Africa, may be little fitted for campaigns conducted under altogether different systems and conditions and against regularly organised European armies. After all that has been said and done, however, have we ever waged a war under the same difficulties that we have had to encounter in South

Africa or, all things considered, more successfully carried out what we set about to accomplish? There can be no doubt that no better equipped and provisioned army has ever been sent by this or any other country into the field. Its shortcomings were mainly attributable to our having under-rated the magnitude of the task, to the sudden and unexpected way in which war was thrust upon us by the Boer ultimatum, and to our having been brought face to face with new problems and a new experience.

The organisation of, and everything connected with, the Army Medical Service will be cast into the melting-pot and subjected to a fierce fire of criticism and rigorous investigation. We shall then see in what respects it is considered susceptible of being remodelled on new and improved lines. The new Government is pledged to undertake the problems, the settlement of which on a practically satisfactory and workable basis becomes more and more difficult. The adjustment of the scales of military and medical requirements, with a due regard to military efficiency and the demands of modern warfare, on the one hand, and progressive requirements of civilised society and sanitation, on the other, is no easy task. But it has to be faced. This brings us to a consideration of Dr. Leigh Canney's proposals and his letter in THE LANCET of Sept. 29th, p. 969. We may first of all take the opportunity of making a few prefatory remarks, if only to guard against any possible misapprehension of what we are about to say. Dr. Canney has, as a matter of course, our entire sympathy in regard to the objects which he has in view. In all that appertains to the sick and wounded soldier and the prevention of disease in the field we cannot fail to be deeply concerned. We heartily welcome every scheme claiming to introduce improvements in these respects and are always prepared to discuss them with a feeling of prejudice in their favour rather than otherwise As a general principle we have always held that what is best for the public is best for the profession, even where, as it occasionally happens, the views put forward may seemingly conflict with some real or alleged professional interest. But this does not remove the responsibility of considering every proposal from a practical and from every other point of view before adopting it. Turning then to Dr. Canney's letter, we disclaim all intention of prejudging his proposals; still we may allude to some points which struck us on reading it, and we follow the order he has laid down

1. The whole public who have been watching their relatives and friends through this anxious struggle, are no doubt immediately concerned, but it would be scarcely possible to submit any proposed remedial measures to the judgment of the public. They must be considered by persons competent to deal with them, and as this war is sure to be followed by an inquiry into everything connected with it and the question of prevention of disease in the field among others, we ventured to suggest that Dr. Canney might very usefully in the public interest take advantage of that opportunity.

2. We wish that we could see how the object of the second paragraph of his letter could be accomplished—viz., to keep the army free from typhoid fever and dysentery from the first day of landing and to discover and to treat suspicious cases. If, as is the case, the mildest cases of typhoid fever are as capable of spreading infection as the gravest this would be a very necessary but a very difficult thing to do But what about the very lengthened periods of time over which it is alleged the infection may extend in those who have apparently recovered from an attack of typhoid fever? We do not see why dust, during such dust-storms as occur in India, for example, should not be a vehicle of infection (if not direct, through articles of food and fluids—say water), notwithstanding that the fact has not yet been scientifically demonstrated. But be this as it may, we freely admit that the main channel of infection is water and that typhoid fever is a water-borne disease, and that if troops could be supplied with sterilised water from start to finish of a campaign a most desirable end would be accomplished. In the case of forced marches such as were carried out by General French, where weight tells and transport is deficient (which is so commonly the case), we nevertheless see some difficulties in the way of doing it.

3. It would, we fear, be simply impossible to be assured of what Dr. Canney demands of medical officers in India; nothing short of an experiment conducted with scientific accuracy would suffice to guard every channel of infection This paragraph appears to us to conflict somewhat with a previous one.

4. This is a matter of opinion and experience. All we can say is that the experience of officers in a campaign has not always been of the same fortunate character.

5. We do not know whether this would, or would not, be practicable under all the conditions of war. Certainly the transport of a "water corps" should be held sacred, but whether all the mules for carrying the boiling machines would be always forthcoming and could accompany and keep pace with the troops under all circumstances is another matter.

In conclusion, we wish to say that although we have criticised some of his proposals we consider that Dr. Canney has been at the trouble to work out a scheme for which he deserves, in our opinion, great credit, and it should receive (as it no doubt will) all the consideration which it merits when the time comes for inquiring into these and other matters connected with the South African War.

THE PLAGUE.

No fresh cases of plague have occurred in Glasgow since the date of our last issue, but the man who was admitted to the Belvidere Hospital from Govan on Sept. 20th died from plague on Oct. 7th.

Dr. A. K. Chalmers has forwarded to us some clinical notes of patients who were reasonably suspected of being affected by plague. We subjoin the notes of two of the most interesting cases.

1. A man sickened on Sept 27th with shivering and headache, which were followed on the 28th by pain in the right axilla. On examination on Oct. 2nd and 3rd there was a a general thickening in this situation, which was tender on pressure, although definite glandular enlargement in the axilla could not be discovered. In the left axilla, however, several glands were enlarged, but were not tender on pressure. He was removed to hospital for observation and in the course of the following day an abscess of a distinctly septic character appeared in the right axilla.

2. On Oct. 6th a boy was notified as suffering from "*fever, probably typhus*," and on the house being visited it was learned that he had died on the previous evening. A history of illness beginning suddenly in the midst of apparently perfect health and accompanied by vomiting and high fever with rapidly increasing prostration and death within 24 hours, aroused suspicion which was strengthened by an external examination of the body and the discovery of a chain of enlarged cervical glands in both sides of the neck and in the left axilla. The body was in consequence removed to the mortuary at Belvidere Hospital and with the father's consent a post-mortem examination was there made. This revealed a tonsillar abscess, with a widely distributed glandular enlargement, all pointing to an extreme degree of susceptibility towards septic poisoning to which the death can be attributed. Evidence of plague was entirely absent.

Professor Zabolotny of the Imperial Institute of Experimental Medicine, St. Petersburg, who in recent years was a member of the Russian expedition for the study of plague in India, Arabia, and Eastern Mongolia, and who spent several weeks in this country on behalf of his Government, has left Glasgow. His conclusions regarding the Glasgow out-break are here reproduced.

1. The epidemic in Glasgow, when compared with that of India, China, and Africa, and with those in Europe of recent years (Oporto, Kolobowka), is of the most mild description.

2. The extension of the epidemic is not great and the mortality is quite insignificant, which may be attributed to the medical and sanitary measures which have been practised with so great energy in Glasgow.

3 For the most part one meets with bubonic cases which are less dangerous from the point of view of epidemiology than the pneumonic forms. These latter are excessively contagious, because the sputum of the sick person teems with plague bacilli.

4. Since in the bubonic form the sickness does not spread except by contact with the skin, the measures of isolation and cleansing of linen and clothing play a most important rôle in prevention.

5. For persons in contact with the sick the best method of protecting them is by preventive injection with serum (from 10 to 20 cubic centimetres) as is practised in Glasgow.

6. Treatment of the patients is most effective when the serum is injected in large doses (from 60 to 120 cubic centimetres) intravenously.

7. The post-mortem examinations of fatal cases have presented a picture of protracted illness (suppuration, *nodules pesteuse*, mixed infection) and not that of an acute malady terminating fatally in from two to three days.

A fatal case of plague occurred at Cardiff on Oct. 4th. The patient was one of the crew of the ship *Southgarth* voyaging from the River Plate to the Tyne. On the way home one member of the crew was put ashore at King's Lynn suffering from typhoid fever—a diagnosis which was made by the medical man who first saw the patient and was subsequently confirmed by the medical officer of health. Another member of the crew who arrived with the ship in the Tyne landed at South Shields on Sept. 22nd. On Sept. 21st he was taken ill. On the 24th he went to North Shields and Newcastle, and from there to his home at Llandaff, where he arrived on the 27th. Here his illness was at first supposed to be typhoid fever, but it was eventually suspected to be plague—a diagnosis which was provisionally confirmed by bacteriological examination of the blood and cultures from the bubo. He was removed to the Cardiff Fever Hospital, where he was isolated and where he died on Oct. 4th. An absolute diagnosis was made from the result of the post-mortem examination and by inoculation of a guinea-pig, a diagnosis which was confirmed by Dr. Klein. By consent of the widow the body of the man was cremated on Flatholm Island. In view of these events the member of the crew of the *Southgarth* who was landed at King's Lynn is being carefully watched. The port medical officer of health, writing on Oct 10th, informs us that the patient is suffering from typhoid fever but is now nearly convalescent. The Local Government Board have issued a "Plague Memorandum" to which we refer in our leading columns.

In view of the possible appearance of the plague in London the Public Health Committee of the London County Council met on Sept 26th and drew up a report which was confirmed by the Council on Oct. 9th. The salient points of this report are as follows. After referring to a communication which had been received from the Local Government Board asking among other things what accommodation the Council could provide for isolating "contacts" the Committee go on to say:—

> We have given careful consideration to the Board's letter and we think it very desirable in the interests of efficiency and economy in administration that the Council should undertake the duty indicated by the Board and should provide the whole of the accommodation required rather than that the duty should be divided among a number of local sanitary authorities. The Council has in its possession a number of properties acquired under various improvement or other schemes some of which could at a few hours' notice be rendered fit for occupation, while the repairs necessary at the others would not take more than a few days. Having regard to the urgency of the matter we have informed the Local Government Board that the Council is prepared to undertake the duty indicated in the Board's letter, and we have sent to the Board a list showing the premises in the Council's possession which could be adapted for the purpose and the time which it would take to render them fit for occupation. We have also stated that, in addition to the premises mentioned in the list, the Council has other buildings which could in case of great emergency be adapted as isolation homes, and that should these eventually prove inadequate the Council would provide or obtain any further accommodation that might be necessary.
>
> We have instructed the valuer, as soon as the Board intimate their acceptance of the Council's offer, to have one of the properties made ready for habitation and the necessary furniture stored therein, to repair two or three of the other properties, and generally to complete lists of furniture, provisional arrangements with contractors, arrangements as to diet, &c., so that the demand for accommodation may be kept pace with should plague appear in London.
>
> We have informed the various committees of the Council which have charge of the properties above referred to, of their proposed use in case of necessity as isolation homes, in which the inmates would be under the daily supervision of the Council's medical officers. Of course the actual cases of plague would be sent to the hospitals of the Metropolitan Asylums Board, while the medical inspection of infected areas and disinfection of premises and articles after cases of plague would no doubt be undertaken by the sanitary authorities.
>
> On Sept. 19th the Local Government Board issued an order requiring the immediate notification of all cases of plague to the sanitary authorities and to themselves. This order applies throughout England and Wales. Under our instructions the medical officer has sent a circular letter to the various medical officers of health in London inviting them to give him immediate notice of cases or suspected cases of plague, with a view to these cases being inquired into by a medical man familiar with the disease, and also with a view to material, if necessary, being sent for bacteriological examination at the cost of the Council. Mr. James Cantlie, M.B., F.R.C.S., formerly medical officer in one of the plague hospitals in Hong Kong, has had large experience of the disease, and we have retained him to examine and report upon any suspected cases of plague in London in which there is any doubt as to the diagnosis, and to make post-mortem examinations when necessary. An arrangement has also been made with Dr. Klein for the bacteriological examination of material from suspected cases.
>
> During the recess the medical officer, under the authority of our chairman, asked Mr. Cantlie to prepare a memorandum giving an account of the clinical characteristics of plague, and we have given instructions for a printed copy of this memorandum to be sent to each medical practitioner in London.
>
> The Council may like to know that in 1898, certain cases of plague having occurred among the members of a ship's company in the Albert Docks, the medical officer caused inquiry to be made by the Council's inspectors in all common lodging-houses, shelters, and seamen's lodging-houses in sanitary districts in the eastern half of London on both sides of the Thames for cases of sickness which might possibly prove to be plague, and all cases of sickness of a doubtful nature were inquired into by one of the Council's medical officers. In July of this year this inquiry was repeated, and it was again repeated in the middle of September. No single case can be found that raises suspicion of plague. All the premises referred to are now being periodically visited for the same purpose, the seamen's lodging-houses [illegible] have not so far entailed much [illegible] me prevalent in London—which we hope will not be the case—of course the Council may have to incur considerable expense for the repair and furnishing of premises as isolation homes and for the food of persons sent to these homes. We propose at our next meeting to consider the question of expenditure and to submit an estimate to the Finance Committee.

LUNACY IN IRELAND.

IN the Forty-ninth Annual Report of the Inspectors of Lunatics (Ireland), just published, the number of the insane in the various institutions in Ireland on Jan. 1st, 1900, was 20,863, as compared with 20,304 patients on Jan. 1st, 1899, or a total increase of 559 patients during the year. The increase has taken place entirely in the district asylums, a decrease being noted in private asylums and workhouses. The increase during 1899 was less than that for the preceding year, which reached the exceptional figure of 714 but was greater than the average increase for the previous 10 years—viz., 475. No provision exists in Ireland by which any returns can be obtained of pauper lunatics wandering at large or residing with relatives except through the decennial census. The number of patients discharged as recovered during the year was 1338 (745 men and 593 women), an increase of 59 over that of the previous year, or 8·5 per cent. of the total average number resident. The number of deaths during the year amounted to 1132, of whom 631 were males and 501 were females. This number exceeded by 27 the mortality of the preceding year and showed a percentage of 7·2 on the average number resident during the year—that for the preceding year being 74. One of the deaths was by suicide and four resulted from misadventure. In 311 cases the cause of death was verified by post-mortem examination, as against 298 for the previous year. The causes of death vary in different localities and are affected by the position of the district from which the patients are received, whether urban or rural, as well as the other manifold conditions which influence the general health, such, for instance, as whether the district is poor or comparatively prosperous. In some instances the causes appear to affect the patients after admission, such as overcrowding. "It is not difficult to understand how such a disease as consumption, which is so common a cause of death in the general population, should be a potent factor in the mortality of asylums; but it is not so easy to explain how other diseases, such as dysentery, not so commonly met with in the outside community, should be found as the cause of death in certain asylums." The number of deaths in district asylums during the year was 1132 and the deaths from general paralysis of the insane amounted to 50, thus showing the progress of this disease amongst the urban population of Ireland. The deaths from consumption amounted to 321, or 28·4 per cent. of the total number. In the Richmond District Asylum the mortality from phthisis was 36·5 per cent., in Cork it was 37 per cent, in Limerick it was 39 per cent., and in Ennis Asylum it was 60 per cent. General paralysis was returned as the cause of 9·7 per cent. of deaths in Waterford Asylum, and 10 6 per cent. in Downpatrick, 13·5 per cent. in Richmond, and 15·7 per cent. in Belfast Asylums. The expenditure incurred in maintaining an average number of

15 785 lunatics in district asylums was £386,306. To meet this expenditure a sum of £211,902 10s. was paid out of the local rates (in pursuance of the 58th section of the Local Government Act of 1898), £153,467 5s. was received by way of Government capitation grant, and £7342 12s. was contributed by the relatives of patients. The average cost per head for all district asylums was £33 9s. 8d. per annum, or 9s. 5d. per head per week.

LEICESTER NEW ISOLATION HOSPITAL.

THE formal opening of the Leicester New Isolation Hospital, the ultimate cost of which will be nearly £60,000, took place on Sept. 28th. There is still a good deal of work to do before the buildings leave the contractors' hands but when finished it is believed that Leicester will possess the finest equipped and most up-to-date institution of the kind in the United Kingdom The Sanitary Committee promoted a competition for the best design, and Messrs. Blackwell and Thomson, architects, of Leicester, gained the first award, and from these designs the hospital has been built. The site comprises about 14 acres. The hospital proper consists of four separate one-storey pavilions for the treatment of scarlet fever, giving accommodation for 26 beds each; a similar pavilion for typhoid fever containing 28 beds; two isolation pavilions—one a two-storey building—containing 28 beds, giving a total accommodation for 160 adult patients. The buildings have been so arranged that two additional scarlet fever pavilions can be easily added and also one additional isolation pavilion. It is suggested that the separate rooms in the isolation blocks can be conveniently used for typhoid fever patients should occasion arise, hence an additional typhoid fever block is not projected. The other buildings comprise the administration block, discharging block, and mortuary. The total number of beds if the full extension were carried out would be 240. The several buildings are connected by macadam roads without covered ways, the ambulance vans thus being able to drive up to the door of each block. The site has an average elevation of about 280 feet above ordnance datum. The four scarlet fever pav t of two main wards, 72 12 beds each. In the ce *or observation* ward of two beds. The nurses' kitchen is centrally placed and can overlook the beds in the two main wards by means of observation windows. At the end of each main ward is placed on one side the sanitary tower containing the water-closets, slop and scalding sinks, which are disconnected by a ventilated lobby, and on the other side the bath-room, containing two baths and two lavatories. The baths are of porcelain with the latest kind of fittings. In connexion with the w has b flushi

The typhoid fever pavilion is very similar to the scarlet fever pavilions with the exception that there are two separate wards instead of one. The one-storey isolation hospital is based on the lines of the Local Government Board's suggestion and provides for a total of 12 beds.

The administration block contains on the right of the front main entrance: committee-room, resident medical officer's sitting room, lavatory, &c., dispensary, laboratory store, waiting-room, and telephone inclosure; and on the left of the entrance matron's sitting-room, office, nurses' mess-room, sitting-room, sewing-room, household linen-room, dry-goods store, lavatory, and servants' hall. The main corridor is seven feet wide. At the west end of the administration block and at right angles to the main corridor is another corridor out of which lead the kitchen and stores. It is proposed to do most of the cooking by gas and by steam. The floors of the corridors, kitchens, &c., are of terazzio, an Italian process by which small pieces of marble are mixed with concrete and a smooth surface is obtained. The first floor contains the nurses' and matron's bedrooms, with bath-rooms, water-closets, and linen store The medical officer's bedroom and bath-room are also on this floor and are approached by a separate staircase. 20 bedrooms for nurses are provided on this floor. The second floor contains 10 bedrooms for servants, a bath-room, &c. The front elevation of the administration block is a neat example of eighteenth century English work. There is nothing in the shape of ornamentation, but in the face of the wall over the portico the name and date of the erection of the hospital are set out in stucco. The porter's lodge is situated on the right-hand side of the main entrance and stands 15 feet back. At the rear of the porter's lodge is the discharging block, arranged in duplicate for male and female patients. The discharged patients will enter the building at one end in hospital garments, will undress and bathe, and will leave by an opposite door, a waiting-room being provided for their friends who come to meet them. The mortuary consists of a post-mortem room, mortuary, and viewing chamber.

The hospital is heated by low-pressure steam, with auxiliary stoves and grates. Ventilating radiators are placed in the wards under some of the windows and extraction flues are built in the outside walls for carrying away the vitiated air of the wards The foul drains from the scarlet fever pavilions, the typhoid fever pavilion, the isolation block, and the administration block are kept quite distinct and are properly disconnected at a manhole before entering the ejector house. The sewage is then pumped up into one of the main carriers on the sewage farm by means of a here is telephonic communication and the hospital is lighted by laundry is fitted with the most modern requisites, the drying chambers being heated with hot air. The laundry is also provided with a large steam disinfector.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6087 births and 3964 deaths were registered during the week ending Oct. 6th. The annual rate of mortality in these towns, which had been 18 1 and 18 5 per 1000 in the two preceding weeks, declined again to 17 8 last week. In London the death-rate was 15 8 per 1000, while it averaged 19·1 in the 32 provincial towns. The lowest death-rates in these towns were 8 7 in Croydon, 13·8 in Nottingham, 14·2 in Cardiff, and 14 3 in Brighton; the highest rates were 24·1 in Norwich, 24 8 in Salford, 25·1 in Sunderland, and 26 0 in Manchester. The 3954 deaths in these towns included 673 which were referred to the principal zymotic diseases, against 771 and 776 in the two preceding weeks; of these 406 resulted from diarrhœa, 92 from diphtheria, 66 from "fever" (principally enteric), 49 from whooping-cough, 32 from scarlet fever, and 28 from measles. The lowest death-rates last week from these diseases occurred in Croydon, Plymouth, Cardiff, Halifax, and Bradford; and the highest rates in Norwich, Leicester, Burnley, Sheffield, Sunderland, and Gateshead. The greatest mortality from measles occurred in Swansea, Huddersfield, and Newcastle; from whooping-cough in Preston and Gateshead; from "fever" in Portsmouth, Swansea, Sheffield, and Sunderland; and from diarrhœa in Norwich, Burnley, Sunderland, and Gateshead. The mortality from scarlet fever showed no marked excess in any of the large towns. The 92 deaths from diphtheria included 29 in London, 11 in Leicester, nine in Leeds, seven in Liverpool, and seven in Sheffield. No fatal case of small-pox was registered last week in any of the 33 towns; and only one small-pox patient remained under treatment in the Metropolitan Asylums Hospitals on Saturday last, Oct. 6th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2071, against numbers increasing from 1703 to 1938 on the five preceding Saturdays; 313 new cases were admitted during the week, against 243, 269, and 318 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 203 and 187 in the two preceding weeks, further declined last week to 164 and were 53 below the corrected average. The causes of 45, or 1·1 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Salford, Bradford, and in 11 other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Liverpool, Manchester, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·9 per 1000 in each of the three preceding weeks, rose to 19·3 per 1000 during the week ending Oct. 6th, and was 1·5 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 13·5 in Perth and 15·3 in Paisley to 21·2 in Aberdeen and 23·2 in Greenock. The 595 deaths in these towns included 53 which were referred to diarrhœa, 18 to whooping-cough, 13 to "fever," 10 to measles, seven to scarlet fever, five to diphtheria, and one to small-pox. In all, 107 deaths resulted from these principal zymotic diseases, against 112 and 91 in the two preceding weeks. These 107 deaths were equal to an annual rate of 3·5 per 1000, which was 0·5 above the mean rate last week from the same diseases in the 33 large English towns. The deaths from diarrhœa, which had been 62 and 49 in the two preceding weeks, rose again last week to 53, of which 26 occurred in Glasgow, 10 in Dundee, six in Edinburgh, five in Paisley, and four in Aberdeen. The fatal cases of whooping-cough, which had declined from 25 to 12 in the five preceding weeks, rose again to 18 last week, and included nine in Greenock, seven in Glasgow, and two in Edinburgh. The deaths referred to different forms of "fever," which had increased from four to 12 in the four preceding weeks, further rose last week to 13, of which 11 (including one fatal case of bubonic plague), were registered in Glasgow and two in Dundee. The deaths from measles, which had been five in each of the two preceding weeks, increased to 10 last week, and included six in Glasgow and three in Edinburgh. The fatal cases of scarlet fever, which had been four and six in the two preceding weeks, further rose last week to seven, of which five occurred in Glasgow. The five deaths from diphtheria showed a decline from recent weekly numbers and included three in Edinburgh and two in Glasgow, where the fatal case of small-pox was also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 101 and 100 in the two preceding weeks, decreased to 98 last week, but were 27 above the number in the corresponding period of last year. The causes of 27, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·5 per 1000 in each of the two preceding weeks, rose to 26·0 during the week ending Oct. 6th. During the past four weeks the death-rate in the city has averaged 25·0 per 1000, the rate during the same period being 16·4 in London and 18·7 in Edinburgh. The 174 deaths belonging to Dublin registered during the week under notice showed an excess of 10 over the number in the preceding week, and included 36 which were referred to the principal zymotic diseases, against 31 and 25 in the two preceding weeks; of these 27 resulted from diarrhœa, five from whooping-cough, three from "fever," and one from measles. These 36 deaths were equal to an annual rate of 5·4 per 1000. the zymotic death-rate during the same period being 2·2 in London and 2·4 in Edinburgh. The fatal cases of diarrhœa, which had declined from 27 to 18 in the three preceding weeks, rose again to 27 last week. The deaths from whooping-cough, which had been three in each of the two preceding weeks, increased last week to five. The fatal cases of "fever," which had been seven, three, and four in the three preceding weeks, declined again to three last week. The 174 deaths in Dublin last week included 66 of infants under one year of age and 28 of persons aged upwards of 60 years; the deaths of infants considerably exceeded the number in the preceding week, while those of elderly persons showed a slight decline. Eight inquest cases and seven deaths from violence were registered, and 54, or nearly a third, of the deaths occurred in public institutions. The causes of 16, or more than 9 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING SEPTEMBER, 1900.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the 43 sanitary areas of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 8·7 per 1000 of the population, estimated at 4,589,129 persons in the middle of the year. In the three preceding months the rates had been 6·9, 7·0 and 6·0 per 1000 respectively. The rates were considerably below the average in Paddington, St George Hanover-square, St. James Westminster, St. Martin-in-the-Fields, Strand, and Woolwich; while they showed the largest excess in Fulham, St. George-in-the-East, St. Saviour Southwark, St. George Southwark, Rotherhithe, and Lee sanitary areas. One small-pox case was notified during September, and was that of a person belonging to Wandsworth sanitary area; one small-pox patient was admitted into the Metropolitan Asylums Hospitals during the month, and two remained under treatment on Saturday, Sept. 29th. The prevalence of scarlet fever showed a marked increase over that recorded in the preceding month; among the various sanitary areas this disease was proportionally most prevalent in Hammersmith, St. Giles, St. Saviour Southwark, St. George Southwark, Lee, and Plumstead. The Metropolitan Asylums Hospitals contained 1899 scarlet fever patients at the end of September, against 1788, 1804, and 1657 at the end of the three preceding months; the weekly admissions averaged 255, against 202, 210, and 152 in the three preceding months. The prevalence of diphtheria showed a considerable increase over that recorded in the preceding month; the greatest proportional prevalence of this disease occurred in Fulham, Mile End Old Town, Poplar, Newington, Bermondsey, and Lee sanitary areas. There were 1231 diphtheria patients in the Metropolitan Asylums Hospitals at the end of September, against 1212, 1256, and 1171 at the end of the three preceding months; the weekly admissions averaged 185, against 151, 183, and 142 in the three preceding months. The prevalence of enteric fever was considerably in excess of that recorded in recent months; among the various sanitary areas this disease was proportionally most prevalent in Chelsea, St. George-in-the-East, St. Saviour Southwark, St. George Southwark, Bermondsey, and Rotherhithe. The Metropolitan Asylums Hospitals contained 329 enteric fever patients at the end of September, against 148, 129, and 170 at the end of the three preceding months; the weekly admissions averaged 69, against 21, 20, and 32 in the three preceding months. Erysipelas was proportionally most prevalent in St. Giles, St Luke, Whitechapel, St. George-in-the-East, Mile End Old Town, and St. Olave Southwark sanitary areas. The 15 cases of puerperal fever included three in St. Pancras, three in Battersea, and two in Greenwich sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the public institutions of London having been distributed among the sanitary areas in which the patients had previously resided. During the four weeks ending Sept. 29th the deaths of 5793 persons belonging to London were registered, equal to an annual rate of 16·5 per 1000, against 14·8, 15·7, and 19·4 per 1000 in the three preceding months. The lowest death-rates last month in the various sanitary areas were 9·1 in Stoke Newington, 9·5 in St. George Hanover-square, 9·9 in St. Martin-in-the-Fields, 10·0 in Hampstead, 12·0 in Paddington, and 12·2 in Kensington; the highest rates were 21·9 in Clerkenwell, 22·8 in Bermondsey and in Rotherhithe, 23·0 in Poplar, 24·8 in Woolwich. 25·0 in St. George Southwark, and 27·7 in St. George-in-the-East. During the four weeks of September 1078 deaths were referred to the principal zymotic diseases in London; of these, 61 resulted from measles, 15 from scarlet fever, 105 from diphtheria, 163 from whooping-cough, 64 from enteric fever, and 670 from diarrhœa. No death from any of these diseases occurred last month in St. Martin-in-the-Fields; in the other sanitary areas they caused the lowest death-rates in Paddington. Kensington, St. George Hanover-square, Strand, City of London, and St. Olave Southwark; and the highest rates in Fulham. St. George-in-the-East, Poplar, St. George Southwark Bermondsey, and Woolwich. The 61 deaths from measles were 16 below the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Clerkenwell, Bethnal Green, St. George-in-the-East, Limehouse Poplar, and St. George Southwark sanitary areas. The 15 fatal cases of scarlet fever were only one-fifth of the corrected average number; the greatest proportional mortality from this disease occurred in Fulham, Holborn, Clerkenwell, Whitechapel, Limehouse, and St. George Southwark. The 105 deaths from diphtheria showed a decline of 75 from

* Including 13 cases of membranous croup.

† Including deaths from membranous croup.

the average number in the corresponding periods of the ten preceding years; among the various sanitary areas this disease was proportionally most fatal in Fulham, Hampstead, Bethnal Green, Poplar, Rotherhithe, and Plumstead. The 163 fatal cases of whooping-cough were 45 in excess of the corrected average; this disease showed the highest proportional fatality in Fulham, St. George-in-the-East, St. George Southwark, Newington, Camberwell, and Greenwich sanitary areas. The 64 deaths referred to enteric fever almost corresponded with the average number; among the various sanitary areas the death-rate from this disease was highest in Chelsea, St. George-in-the-East, Poplar, Bermondsny, Rotherhithe, and Lewisham (excluding Penge). The 670 deaths from diarrhœa were 153 in excess of the corrected average; this disease was proportionally most fatal in St. Luke, St. George Southwark, St. Saviour Southwark, Bermondsey, Lewisham, and Woolwich sanitary areas. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during September was nearly 5 per cent. above the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 196 per 1000. The lowest rates of infant mortality were recorded in St. George Hanover-square, Marylebone, Hampstead, Stoke Newington, St. Martin-in-the-Fields, and Plumstead; and the highest rates in Westminster, Clerkenwell, Poplar, Rotherhithe, Woolwich, and Lee sanitary areas.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon E. H. Williams is placed on the retired list. Staff Surgeons J. J. Dinnis and G. F. Wales to be Fleet Surgeons.

ROYAL ARMY MEDICAL CORPS.

Major A. E. Morris is granted 90 days' privilege leave from India to Australia.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Harry Munyard Brownfield, 3rd Volunteer Battalion the Hampshire Regiment, to be Surgeon-Lieutenant. Surgeon-Lieutenant James Steel Swain, 2nd Tower Hamlets Volunteer Rifle Corps, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the East Yorkshire Regiment: Samuel Harvard Johnson to be Surgeon-Lieutenant. 4th (Perthshire) Volunteer Battalion the Black Watch (Royal Highlanders): William Haig to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Essex Regiment: John Elsdale Molson to be Surgeon-Lieutenant. 1st (Cumberland) Volunteer Battalion the Border Regiment: Surgeon-Lieutenant S. Maclean resigns his commission. 4th London: Frederick James Purcell Daly to be Surgeon-Lieutenant.

TRANSVAAL WAR NOTES.

Civil Surgeon Barras and Civil Surgeon McKitchen are returning to England in the *Bulawayo*, which also has on board among the sick and wounded Civil Surgeon Miller.

TRANSVAAL WAR CASUALTIES.

Lieutenant L. E. L. Parker, R.A.M.C., is reported to have received a slight gunshot wound in the right hand.

MENTIONED IN DESPATCHES.

The despatches from Admiral Seymour relative to the recent attempted relief of Pekin contain the following paragraphs:—"Fleet Surgeon Thomas M Sibbald, H.M.S. *Centurion*, has had charge of the hospital arrangements throughout, and has also been much under fire. His activity, attention, and constant cheerfulness have gone far to mitigate the sufferings of the wounded and have met with my entire approval."

"Surgeon J. Falconer Hall of H.M S. *Barfleur*, whose devoted care and attention to his patients (as well as his professional skill) during a most trying time have been the admiration of all."

THE NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on Oct. 9th, Sir J. N. Dick, K.C.B., being in the chair, the sum of £28 was distributed among the several applicants.

The *Army and Navy Gazette* of Oct. 6th says: "It will interest Mr. Burdett-Coutts and others, no doubt, to learn that in China every attempt is being made to provide for all contingencies, so far as hospital arrangements are concerned, the establishment having been fixed on the most liberal terms. For the European portion, numbering in all about 1000, ten beds for officers and 200 for men in the field and general hospital have been provided. This is in addition to the hospital ship *Maine*, containing 175 beds. For the native portion of the force, numbering in all, including non-combatants, about 30,000, there are 1300 beds in native field hospitals, 1500 in the general hospitals, 200 on the line of communications; also two hospital ships containing about 365 beds, and 500 beds in the General Hospital, Calcutta. The *personnel* sent to China comprises 135 medical officers, 35 assistant surgeons, 25 native hospital assistants, and 224 nurses. All the hospitals are fully equipped, the ambulance includes 180 bearers to each field hospital and nine ambulance tongas. A complete conservancy establishment accompanies each hospital. We are assured by a correspondent, a medical officer, that 'the utmost care was taken by the military authorities in India to prevent any failure of system, it being recognised that the difficulties of the campaign may be great, and with a trying climate to face the native troops might feel the strain greatly. But the care with which every detail is worked out ought to be a guarantee that the troops will be well cared for.'"

Major R. H. Firth, R.A.M.C., has been selected to succeed Colonel J Lane Notter, R.A.M.C., as Professor of Military Hygiene at the Army Military School, Netley.

Correspondence.

"Audi alteram partem."

"THE NOTIFICATION OF PLAGUE."

To the Editors of THE LANCET.

SIRS,—The letter of Dr. Colvin in THE LANCET of Oct. 6th (p. 1040), under this title, revives in my mind an impression which has been present to me ever since the Notification Act has been in operation—viz., that it is most unfortunately constructed in respect of the *name* of the disease being required as an almost essential element in the notification. What is desirable in the public interest is the earliest possible communication to the sanitary authority, not of a fully formed diagnosis, but of even a reasonable suspicion, founded on stateable facts, of infection. In the early cases of plague in Glasgow, for example, no one (medical or otherwise) was concerned in any of them who had ever seen a case of plague, and much credit is justly due to those who even hesitatingly approximated to a correct diagnosis under these circumstances. Yet here is a case (as indicated by Dr. Colvin) which, though plainly one of bubonic plague and arising, moreover, in distinctly traceable association with other cases, was 18 days suffering under acute symptoms before Dr. Colvin was called and from his previous experience was able to give the disease a name. It is quite true that there was "no regular medical attendance," and perhaps no one was to blame for this. But is it not quite obvious now that a woman who had a temperature of 104° F. when first casually seen, who was "raving" even at the commencement of her disease, and who "had been to the wake in Rose-street" and otherwise in association with other cases removed to hospital as being cases of an infectious disease, ought to have been at once reported to the authorities whether with or without a diagnosis? It is a matter of notoriety that the reporting of cases under the Act is often deferred for days (if not for weeks) till the diagnosis is made perfectly clear, and medical men have even been blamed for reporting cases which have not turned out to be what at first it was supposed they might be. In my opinion the Act ought to have been so constructed that every case, not only of fully-formed infectious disease, but every case in which a reasonable presumption of infection exists (as of even indefinite illness in an infected locality) should be at once reported, leaving the diagnosis in some cases to follow the notification; and, further, some inducements ought to be held out to make such notifications (not necessarily by medical r [illegible] medical language) to all persons [illegible] the sick, or even living in the [illegible] interested in checking the spread [illegible] No doubt this would lead to a nu [illegible] perhaps even to some designedly false or merely alarmist notifications, but in cases having "no regular medical attendance" the advantage of so notifying is obvious; and even when a medical man is in regular attendance he ought to be stimulated to make the earliest possible notification by the knowledge that if he failed in communicating his partially formed suspicions someone else might do it before him.

I am, Sirs, yours faithfully,

Edinburgh, Oct. 8th, 1900. W. T. GAIRDNER.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY AND THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—In April of this year I received as a circular the annual report of the London and Counties Medical Protection Society in which some severe strictures upon the action of the General Medical Council were introduced. In THE LANCET of March 31st you published a leading article upon those strictures, having evidently assumed that they were well founded. As a member of the Penal Cases Committee of the General Medical Council I was subsequently led to ask the secretary of the London and Counties Medical Protection Society to supply me with the facts of the cases upon which his society had formulated the charge referred to, and on their receipt I re-investigated the three cases with every care.

On May 5th I reported the result of my investigation to Dr. Hugh Woods and his council, and after waiting for an answer more than 20 weeks I received in response to a note of Sept 26th, the following from Dr. Woods "that neither my council nor I considered that a reply was required." I now inclose you my letter of May 5th for publication and you will judge whether it is worthy of an answer or is unanswerable. At any rate, it is to be regretted that a medical protection society should circulate freely an accusation against the General Medical Council—which has only done its duty—based upon such slender material as has been adduced.

I am, Sirs, yours faithfully,

Grosvenor-street, W., Oct. 9th, 1900. THOMAS BRYANT.

[INCLOSURE.]

Letter to Dr. Hugh Woods, Honorary Secretary to London and Counties Medical Protection Society, 12, New-court, Lincoln's-Inn, W.C.

65, Grosvenor-street, Grosvenor-square,
May 5th.

DEAR SI[illegible] 'th thanks the final instal[illegible] I asked for in my letter c[illegible] merits of the cases upon [illegible] Committee of the Gener[illegible] licly founded against th[illegible] e which I now quote from [illegible] ited and freely circulated, *of your society.*

"Your council have reported to the General Medical Council several cases of alleged 'infamous conduct' on the part of professional men. Before reporting such cases your council have *made most careful* [illegible] *of the complaints which have been* [illegible] as reported, some did not go beyond [illegible] ugh supported *by sworn statutory* [illegible] prove conduct usually deemed [illegible] ect, not merely by medical men [illegible] ical Council itself. The grounds on which these cases were refused a hearing by the General Medical Council are not known to the council of your society. And your council *feel bound to further express their opinion that the existing* arrangements of the General Medical Council do not deal adequately with matters of this sort, which [illegible]

[illegible]

cases as furnished by you fr[illegible] answers as supplied to the Gen[illegible] the profession accused of unprofessional conduct by your society—that is, after studying both sides of the questions raised—I have no hesitation in asserting that the conclusions of the Penal Cases Committee in each of the three [illegible]

[illegible]

at the end of this month. In the case of W—— the case was dropped, [illegible]

[illegible] that the accusation was "clearly proved," but you do not state by what [illegible] rge against the General Medical [illegible] le most careful inquiry into the [illegible] "; and then you go on to assert [illegible] *ondoned a clearly proved case."* Might I ask upon what grounds you make such a grave and unjustifiable charge?

In the *second* case "you affirm that an unqualified person employed by a medical man and under his cover was habitually undertaking the [illegible] ou [illegible] a [illegible] a charge against a qualified medical man of having given a death *certificate in the case of* a person *who had not been attended by him* during her last illness, and you add "that the truth of this charge must be assumed, as it was supported by a statutory declaration," and when you heard from the Registrar of the General Medical Council that the committee of the Council was not prepared to recommend the Council to proceed further with the case you calmly claim that you are entitled to see and examine the evidence the Council may have [illegible] it would be interesting to know if this be your custom, for, if so, it is somewhat alarming. The General Medical Council does not follow this line of action; it receives the statutory evidence you or others may supply it with, but does not assume its truth, and before it gives a decision it makes most careful inquiry into the justice and validity of [illegible]

[illegible] consciences can give.

In conclusion, allow me to ask (through you) your council to point out in what way justice has been frustrated in these cases through any action of the General Medical Council, and to state upon what grounds they can justify their unanimous vote for the adoption of the charge against *the General Medical Council* with its *publication* and circulation in the annual report of April 3rd upon such materials as you tell me it has been based? It seems to me, Mr. Secretary, that in your wish "to explain to the members of your society that its action was not in fault in the matter"—and here I quote your words—and in your anxiety to run a tilt against a public body composed of men with some slight intelligence, business capacity, and honesty, you have possibly unintentionally misled your council to adopt unanimously a resolution for publication which is absolutely unjustifiable upon the grounds stated. For had any one member *of your council taken the least trouble to sift* for himself the value of the evidence of unprofessional conduct as advanced in the three now famous cases upon which alone your charges against the Medical Council have been based, and not assumed the truth of the evidence of the accusers, even when put into the form [illegible] unjustifiable charge against a public body upon such trumpery material. You tell me likewise "that you have been authorised by your council to publish detailed accounts of these cases *for* the information *of* the profession." Should you *deem it wise to do so I must ask you to let* me know when you do, as I should wish this correspondence to be published with such details. Should you decide not to give details I still hold myself at liberty to send this correspondence or rather this letter, to the journals, for as your charge against the General Medical Council has been widely distributed it is certainly well that the profession should know upon what grounds it has been made by your society.

Yours faithfully,

THOMAS BRYANT.

AUTO-INFECTION THROUGH THE MOUTH A POSSIBLE CAUSE FOR RELAPSES IN ENTERIC FEVER.

To the Editors of THE LANCET.

SIRS,—Do we ever warn an enteric fever patient not to put his fingers in or near his mouth? I think not. Neither do we instruct his nurse to disinfect his hands and nails as a matter of routine. Amongst the several theories as to the cause of relapse I do not find mention or suggestion of auto-infection through the mouth. The patient is, speaking generally, apathetic and lies without movement for days together; his sordes and his nasal mucous accumulations do not trouble him, and, as Dr. James Barr remarks, "he makes no attempt to remove them." But there are exceptions and the cases of relapse (16 per cent., Shattuck) may occur in those very exceptions—men who are not always contented the average number in the corresponding periods of the ten preceding years; among the various sanitary areas this disease was proportionally most fatal in Fulham, Hampstead, Bethnal Green, Poplar, Rotherhithe, and Plumstead. The 163 fatal cases of whooping-cough were 45 in excess of the corrected average; this disease showed the highest proportional fatality in Fulham, St. George-in-the-East, St. George Southwark, Newington, Camberwell, and Greenwich sanitary areas. The 64 deaths referred to enteric fever almost corresponded with the average number; among the various sanitary areas the death-rate from this disease was highest in Chelsea, St. George-in-the-East, Poplar, Bermondsey, Rotherhithe, and Lewisham (excluding Penge). The 670 deaths from diarrhœa were 153 in excess of the corrected average; this disease was proportionally most fatal in St. Luke, St. George Southwark, St. Saviour Southwark, Bermondsey, Lewisham, and Woolwich sanitary areas. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during September was nearly 5 per cent. above the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 196 per 1000. The lowest rates of infant mortality were recorded in St. George Hanover-square, Marylebone, Hampstead, Stoke Newington, St. Martin-in-the-Fields, and Plumstead; and the highest rates in Westminster, Clerkenwell, Poplar, Rotherhithe, Woolwich, and Lee sanitary areas.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon E. H. Williams is placed on the retired list. Staff Surgeons J. J. Dinnis and G. F. Wales to be Fleet Surgeons.

ROYAL ARMY MEDICAL CORPS.

Major A. E. Morris is granted 90 days' privilege leave from India to Australia.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Harry Munyard Brownfield, 3rd Volunteer Battalion the Hampshire Regiment, to be Surgeon-Lieutenant. Surgeon-Lieutenant James Steel Swain, 2nd Tower Hamlets Volunteer Rifle Corps, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the East Yorkshire Regiment: Samuel Harvard Johnson to be Surgeon-Lieutenant. 4th (Perthshire) Volunteer Battalion the Black Watch (Royal Highlanders): William Haig to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Essex Regiment: John Elsdale Molson to be Surgeon-Lieutenant. 1st (Cumberland) Volunteer Battalion the Border Regiment: Surgeon-Lieutenant S. Maclean resigns his commission. 4th London: Frederick James Purcell Daly to be Surgeon-Lieutenant.

TRANSVAAL WAR NOTES.

Civil Surgeon Barras and Civil Surgeon McKitchen are returning to England in the *Bulawayo*, which also has on board among the sick and wounded Civil Surgeon Miller.

TRANSVAAL WAR CASUALTIES.

Lieutenant L. E. L. Parker, R.A.M.C., is reported to have received a slight gunshot wound in the right hand.

MENTIONED IN DESPATCHES.

The despatches from Admiral Seymour relative to the recent attempted relief of Pekin contain the following paragraphs:—"Fleet Surgeon Thomas M. Sibbald, H.M.S. *Centurion*, has had charge of the hospital arrangements throughout, and has also been much under fire. His activity, attention, and constant cheerfulness have gone far to mitigate the sufferings of the wounded and have met with my entire approval."

"Surgeon J. Falconer Hall of H.M.S. *Barfleur*, whose devoted care and attention to his patients (as well as his professional skill) during a most trying time have been the admiration of all."

THE NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on Oct. 9th, Sir J. N. Dick, K.C.B., being in the chair, the sum of £28 was distributed among the several applicants.

The *Army and Navy Gazette* of Oct. 6th says: "It will interest Mr. Burdett-Coutts and others, no doubt, to learn that in China every attempt is being made to provide for all contingencies, so far as hospital arrangements are concerned, the establishment having been fixed on the most liberal terms. For the European portion, numbering in all about 1000, ten beds for officers and 200 for men in the field and general hospital have been provided. This is in addition to the hospital ship *Maine*, containing 175 beds. For the native portion of the force, numbering in all, including non-combatants, about 30,000, there are 1300 beds in native field hospitals, 1500 in the general hospitals, 200 on the line of communications; also two hospital ships containing about 365 beds, and 500 beds in the General Hospital, Calcutta. The *personnel* sent to China comprises 135 medical officers, 35 assistant surgeons, 25 native hospital assistants, and 224 nurses. All the hospitals are fully equipped, the ambulance includes 180 bearers to each field hospital and nine ambulance tongas. A complete conservancy establishment accompanies each hospital. We are assured by a correspondent, a medical officer, that 'the utmost care was taken by the military authorities in India to prevent any failure of system, it being recognised that the difficulties of the campaign may be great, and with a trying climate to face the native troops might feel the strain greatly. But the care with which every detail is worked out ought to be a guarantee that the troops will be well cared for.'"

Major R. H. Firth, R.A.M.C., has been selected to succeed Colonel J Lane Notter, R.A.M.C., as Professor of Military Hygiene at the Army Military School, Netley.

Correspondence.

"Audi alteram partem."

"THE NOTIFICATION OF PLAGUE."

To the Editors of THE LANCET.

SIRS,—The letter of Dr. Colvin in THE LANCET of Oct. 6th (p. 1040), under this title, revives in my mind an impression which has been present to me ever since the Notification Act has been in operation—viz., that it is most unfortunately constructed in respect of the *name* of the disease being required as an almost essential element in the notification. What is desirable in the public interest is the earliest possible communication to the sanitary authority, not of a fully formed diagnosis, but of even a reasonable suspicion, founded on stateable facts, of infection. In the early cases of plague in Glasgow, for example, no one (medical or otherwise) was concerned in any of them who had ever seen a case of plague, and much credit is justly due to those who even hesitatingly approximated to a correct diagnosis under these circumstances. Yet here is a case (as indicated by Dr. Colvin) which, though plainly one of bubonic plague and arising, moreover, in distinctly traceable association with other cases, was 18 days suffering under acute symptoms before Dr. Colvin was called and from his previous experience was able to give the disease a name. It is quite true that there was "no regular medical attendance," and perhaps no one was to blame for this. But is it not quite obvious now that a woman who had a temperature of 104° F. when first casually seen, who was "raving" even at the commencement of her disease, and who "had been to the wake in Rose-street" and otherwise in association with other cases removed to hospital as being cases of an infectious disease, ought to have been at once reported to the authorities whether with or without a diagnosis? It is a matter of notoriety that the reporting of cases under the Act is often deferred for days (if not for weeks) till the diagnosis is made perfectly clear, and medical men have even been blamed for reporting cases which have not turned out to be what at first it was supposed they might be. In my opinion the Act ought to have been so constructed that every case, not only of fully-formed infectious disease, but every case in which a reasonable presumption of infection exists (as of even indefinite illness in an infected locality) should be at once reported, leaving the diagnosis in some cases to follow the notification; and, further, some inducements ought to be held out to make such notifications (not necessarily by medical men or in medical language) to all persons having anything to do with the sick, or even living in the neighbourhood and thus interested in checking the spread of infectious disease there. No doubt this would lead to a number of ill-considered and perhaps even to some designedly false or merely alarmist notifications, but in cases having "no regular medical attendance" the advantage of so notifying is obvious; and even when a medical man is in regular attendance he ought to be stimulated to make the earliest possible notification by the knowledge that if he failed in communicating his partially formed suspicions someone else might do it before him.

I am, Sirs, yours faithfully,

Edinburgh, Oct. 8th, 1900. W. T. GAIRDNER.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY AND THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—In April of this year I received as a circular the annual report of the London and Counties Medical Protection Society in which some severe strictures upon the action of the General Medical Council were introduced. In THE LANCET of March 31st you published a leading article upon those strictures, having evidently assumed that they were well founded. As a member of the Penal Cases Committee of the General Medical Council I was subsequently led to ask the secretary of the London and Counties Medical Protection Society to supply me with the facts of the cases upon which his society had formulated the charge referred to, and on their receipt I re-investigated the three cases with every care.

On May 5th I reported the result of my investigation to Dr. Hugh Woods and his council, and after waiting for an answer more than 20 weeks I received in response to a note of Sept 26th, the following from Dr. Woods "that neither my council nor I considered that a reply was required." I now inclose you my letter of May 5th for publication and you will judge whether it is worthy of an answer or is unanswerable. At any rate, it is to be regretted that a medical protection society should circulate freely an accusation against the General Medical Council—which has only done its duty—based upon such slender material as has been adduced. I am, Sirs, yours faithfully,

Grosvenor street, W., Oct. 9th, 1900. THOMAS BRYANT.

[INCLOSURE.]

Letter to Dr. Hugh Woods, Honorary Secretary to London and Counties Medical Protection Society, 12, New-court, Lincoln's-Inn, W.C.

65, Grosvenor-street, Grosvenor-square,
May 5th.

DEAR SIR,—I [illegible] with thanks the final instalm[illegible] I asked for in my letter of [illegible] merits of the cases upon t[illegible] Committee of the General Medical Council your society has publicly founded against the General Medical Council the serious charge which I now quote from the last year's report, which has been printed and freely circulated [illegible]

[illegible]

infamous' in a professional respect, not merely by medical men generally, but by the General Medical Council itself. The grounds on which these cases were refused a hearing by the General Medical Council are not known to the council of your society. And your council feel bound to further express their opinion that the existing arrangements of the General Medical Council do not deal adequately with matters of this sort, wh[illegible] medical profession, but also the [illegible]

I now as one of the members [illegible] well to inform you, and throug[illegible] after carefully going over the [illegible] cases as furnished by you fr[illegible] answers as supplied to the Gen[illegible] the profession accused of unprofessional conduct by your society—that is, after studying both sides of the questions raised—I have no hesitation [illegible]

[illegible]

at the end of this mon[illegible]

[illegible]

that the accusation was "clearly proved," but you do not state by what [illegible]rge against the General Medical [illegible]e most careful inquiry into the [illegible]"; and then you go on to assert [illegible]*ondoned a clearly proved case*" Might I ask upon what grounds you make such a grave and unjustifiable charge?

[illegible]

statutory declaration and copy of a death certificate in support of a charge against a qualified medical man of having given a death [illegible] him [illegible]arge [illegible] and [illegible]ncil [illegible] the Council to proceed further with the case you calmly claim that you are entitled to see and examine the evidence the Council may have obtained to enable it to come to a decision when you ought to know that such evidence is confidential and cannot be made public.

It would seem that in the cases you bring before the Medical Council you are satisfied with the statements of the accuser if he be a member of your society, and that you do not trouble to find out from the accused what amount of truth there may be in the accusation. It would be interesting to know if this be your custom, for, if so, it is somewhat alarmin[illegible] not follow this line of action; it [illegible] or others may supply it with, bu[illegible]efore it gives a decision it makes r[illegible] and validity of the complaints which have been submitted to it, and even goes so far—which, I trust, you will not think unfair—as to ask the accused what he has to say upon the charge before judgment is given. In the three cases n[illegible] your charge has been based, [illegible] parties were at once acquitte[illegible]against them, whilst their ac[illegible]ishment than their consciences can give.

In conclusion, allow me to ask (through you) your council to point out in what way justice has been frustrated in these cases through any action of the General Medical Council, and to state upon what grounds they can justify their unanimous vote for the adoption of the charge against the General Medical Council with its publication and circulation in the annual report of April 3rd upon such materials as you tell me it has been based? It seems to me, Mr. Secretary, that in your wish "to explain to the members of your society that its action was not in fault in the matter"—and here I quote your words—and in your anxiety to run a tilt against a public body composed of men with some slight intelligence, business capacity, and hone[illegible]ally misled your council to ac[illegible] publication which is absolutely [illegible]d. For had any one member o[illegible]uble to sift for himself the val[illegible] conduct as advanced in the three now famous cases upon which alone your charges against the Medical Council have been based, and not assumed the truth of the evidence of the accusers, even when put into the form of a statutory declaration, and had he, moreover, sought for some explanation from the accused, his decision would doubtless have been [illegible]

[illegible]

profession. Should you [illegible] me know when you do, as I should wish this correspondence to be published with such details. Should you decide not to give details [illegible] or rather this [illegible]neral Medical [illegible] that the pro[illegible]nade by your society.

Yours faithfully,
THOMAS BRYANT.

AUTO-INFECTION THROUGH THE MOUTH A POSSIBLE CAUSE FOR RELAPSES IN ENTERIC FEVER.

To the Editors of THE LANCET.

SIRS,—Do we ever warn an enteric fever patient not to put his fingers in or near his mouth? I think not. Neither do we instruct his nurse to disinfect his hands and nails as a matter of routine. Amongst the several theories as to the cause of relapse I do not find mention or suggestion of auto-infection through the mouth. The patient is, speaking generally, apathetic and lies without movement for days together; his sordes and his nasal mucous accumulations do not trouble him, and, as Dr. James Barr remarks, "he makes no attempt to remove them." But there are exceptions and the cases of relapse (16 per cent., Shattuck) may occur in those very exceptions—men who are not always contented to lie still and allow their noses to become blocked and not to move a finger to put matters right. The patient's hands, as a rule, lie by the side of his body; would it be a great wonder if not his hands alone but his nails especially became infected with his own dejecta? Surely not; in spite of the best nursing it must frequently, if not always, occur. In those more restless cases up goes the hand to the mouth or nose and bacillary re entry takes place.

When enteric fever is at its height during the second or third week the bacillus presumably is most poisonous, and it is probably at that period (judging from temperature charts) when, if the patient is of a "picking" nature, the re-infection is brought about.

In Allbutt's "System of Medicine" the writer remarks in speaking of a relapse that "in most cases it occurs within the first fortnight of convalescence." This observation, estimating the incubative period at from 10 to 14 days, carries us back to the time of high fever. Therefore, if a relapse is going to occur, the re-infection takes place when the patient is half way through his illness. If my theory be correct that the patient's hands are the cause of the relapse, the usual apathy of the sufferer in enteric fever is a potent factor in preventing its occurrence. But we have a safeguard against re-infection if only we take advantage of it—I mean *time*. Fresh typhoid stools are *not* infectious and only become so after one or more days (Murchison, Cayley). The bacilli are anaerobic when first passed (Huppe) and apparently must have time to become aerobic to be infectious.

Theoretically, then, we ought to be on the safe side if we order disinfection of the hands, &c., once in 24 hours, for where is the most likely place for the bacillus to pass the waiting period before returning to the bosom of his family if not the nails? I suggest, therefore: 1. A relapse is caused by the unclean hands or nails of the patient himself. 2. That the re-admission of the bacillus takes place at the period of high fever. 3. That the incubation period of the relapse is probably as lengthy as that of the initial attack. 4. That his hands, &c., should be disinfected at least every 24 hours and his bed-gear changed as frequently. (Carbolic acid from 2 to 3 per cent. or corrosive sublimate 1 in 5000 kills the bacillus quickly.)

Since writing the above I find that Dr. Horton-Smith in his Goulstonian Lectures (p. 30) remarks upon the difficulty of finding the typhoid bacillus in alvine discharges after the third week, and in Allbutt's "System of Medicine" (p. 822) occur the words: "The typhoid bacillus has not been found in alvine discharges before the ninth day." These two references agree with my suggestion of the probability of reinfection at the period of high fever and it seems to me, therefore, that we ought to be particularly careful in disinfecting between the ninth and the twenty-first days.

It is only by routine disinfection of cases in hospitals that any reliable statistics can be obtained, and I trust that others will follow the lead of St. Thomas's Hospital, where at my suggestion disinfection of the hands, &c., is now practised. I do hope this theory will not be held to be too "sweetly simple" for belief or rather for a trial of the effect of disinfection. Who knows but that by this means we may be able to banish relapse from our practices and text-books?

I am, Sirs, yours faithfully,
George W. Ord, M.R.C.S. Eng., L.R.C.P. Lond.
Queen's-road, Richmond, Oct. 9th, 1900.

"THE ETIOLOGY OF RHEUMATIC FEVER."

To the Editors of THE LANCET.

Sirs,—The valuable observations of Dr. F. J. Poynton and Dr. Alexander Paine[1] have at length corroborated those recorded by myself in your journal with regard to the invariable presence in the blood of patients suffering from rheumatic fever of a specific organism, which as long ago as 1892[2] you can by reference to your files ascertain that I described as a minute coccus, and concerning which last March[3] I specifically expressed my ability to demonstrate in any selected case of rheumatic fever. My method of demonstration is somewhat different to that described by Dr. Poynton and Dr. Paine and in the hope of assisting those gentlemen I venture to publish the fact that if the cover-glass preparation is immersed for a few minutes in a solution of bicarbonate of potash the organism can then be most effectively stained with methylene blue. In dealing with rheumatic fever this affords a most practical means of prognosis, as frequently, after all fever has abated, the micrococci present in the blood convey an intimation for the necessity of continued treatment; therefore it has been my custom to administer salicylate of soda until all micrococci have disappeared. With regard to the large bacillus of Achalme I described that also in 1892,[4] but in association with acute gout, of which disease I believe it to be the cause, more especially as I have grown the organism upon nutrient agar agar with the production of uric acid in the test-tube. I am not in a position to continue the necessary experiments, but possibly my investigations may assist others better able to inquire further. My observations were published in The Lancet and reference to the old files will, I believe, establish the fact that they were prior to the continental discoveries quoted by Dr. Poynton and Dr. Paine. At the time that I made the statements I felt that my own unaided and unsupported records were hardly of sufficient weight to be of much importance. I made several attempts to get more senior authorities to interest themselves in the question, but in 1893 the position of bacteriology was rather uncertain; at last, however, the work of Dr. Poynton and Dr. Paine will, I trust, meet with that appreciation which it deserves and will help to rid this country of, or at any rate to mitigate, one of the most destructive ailments to which the human race is liable. Dr. Poynton and Dr. Paine have made a grand series of investigations which will probably be better appreciated in 10 years' time than at the present moment.—I am, Sirs, yours faithfully,

Edward F. Grun, M.R.C.S. Eng., L.R.C.P. Lond.
Southwick, Brighton, Oct. 4th, 1900.

"THE SMOKE NUISANCE."

To the Editors of THE LANCET.

Sirs,—As health officer of a local authority the members of which are only too anxious to put down the smoke nuisance in their district may I point out to your correspondents "W. B. Richmond" and "L. R." certain facts which I think may be of great interest to them and to the public at large.

I inclose a copy of a report to my Sanitary Committee, presented to my Board last night, and upon p. 37 you will find the following extract upon smoke consumption.

> *Smoke Consumption.*
>
> The smoke consumption in a district such as Poplar forms a very important item in conserving the health of the inhabitants, and there can be no doubt that the smoke consumption being watched by all the sanitary officers on their respective areas, the nuisance arising from the neglect of such consumption will be more quickly abated.
>
> As explained to the Sanitary Committee at their last meeting great care will have to be observed before instituting legal proceedings for obtaining penalties in respect of smoke nuisances, as it must be ascertained at the time of the nuisance who is the person guilty—the master, under Section 23 (1) of the Public Health (London) Act, 1891, in not having proper appliances, or the servant under Section 23 (2)[1] of the Public Health (London) Act, 1891, for not using such appliances. Of course, the fuel used will have to be taken into consideration. Section 23 deals with smoke consumption as a specific offence, but Section 24[2] deems smoke to be a nuisance requiring the service of statutory documents, and the master is held to be responsible even if his servant be negligent.

By Section 23 (5) of the Public Health (London) Act, 1891:—

> It shall be the duty of every sanitary authority to enforce the provisions of this section and an information shall not be laid for the recovery of any fine under this section except under the direction of a sanitary authority.

But by Section 24 of the same Act smoke nuisances

> Shall be nuisances liable to be dealt with summarily under this Act and the provisions of this Act relating to those nuisances shall apply accordingly.

Now it appears to me that by Section 12 (1) of the Public Health (London) Act, 1891, *any person* can take action for proceedings in respect of nuisances under Section 24 of the Public Health (London) Act 1891.

> Section 12.—(1) Complaint of the existence of a nuisance liable to be dealt with summarily under this Act on any premises within the district of any sanitary authority may be made by any person, and thereupon the like proceedings shall be had with the like incidents and

consequences as to making of orders, fines for disobedience of orders, appeal, and otherwise, as in the case of a like complaint by the sanitary authority.

So that the Coal Smoke Abatement Society can take action for smoke nuisances in the same manner under Section 12 (1) of the Public Health (London) Act, 1891, as the Mansion House Council take action in the case of other nuisances—viz., by applying for summonses in order to procure abatement or prohibitory orders.

I am, Sirs, yours faithfully,
FREDERICK WM. ALEXANDER,
Medical Officer of Health, Poplar and
Bow road, Bow, E., Oct. 10th, 1900. Bromley.

THE POSITION OF COLONIAL MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—Now that we read and hear so much of the grievances of the medical departments of the army and navy it may not be out of place to bring forward the conditions under which colonial medical officers are required to serve on the west coast of Africa, most of whom, it is well to remember, have had "war experience" in the many punitive expeditions which are so frequent in that unknown and benighted country. With the exception of Nigeria, which may be said to be in a state of evolution at present, the following conditions apply to the other British possessions (I cannot call them colonies) on the west coast.

1. *Pay.*—From £300 to £500 by varying increments annually, biennially, triennially, as the case may be.

2. *Pension.*—There are only two conditions under which a pension can be drawn: (*a*) old age (one man alone draws a pension under this head); and (*b*) bad health; if an officer is permanently invalided out of the service and has already served seven years he is al
multiplied by the number of
I should mention the existe
having served 10 years is allowed to add five years to the time served, but nobody seems to benefit by it. The fact remains that when the invalid comes home he is allowed nothing in proportion to his service.

3. *Quarters.*—Most, if not all, of the quarters supplied are not fit to put Europeans to live in in the tropics.

4. *Allowances.*—10*s.* per diem may be said, generally speaking, to be the allowance, whether travelling or fighting, it does not matter which.

5. *Messing.*—No provision whatever is made in this most important branch of tropical hygiene.

6. *Leave.*—Six months' leave for every 12 months' service. This is as it should be.

The above, with the exception of No. 6, are not enticing and can only be considered repellent when applied to such an unhealthy climate. It is notorious that service under the Colonial Office is unpopular, and now that candidates are scarce it is impossible to fill any vacancies. Here, by the way, I may draw attention to the fact that a lady doctor has just been appointed to the Ashantee Expeditionary Force The Ashantee revolt which is now raging, though overshadowed by events in South Africa and China, has been the means of bringing to notice several medical men who, though nominally "civilian," have done their share of fighting which has caused them to be mentioned for their bravery and devotion under the most trying circumstances it is possible to imagine. The rules governing employment under the Colonial Office are out of date and should at once be redrafted to meet the requirements of a rapidly growing department. There are at the present time over 100 colonial surgeons on the west coast of Africa It is easy as a rule to complain, but not always easy to suggest a remedy; fortunately in this case the treatment is obvious.

1. *Pay.*—From £400 to £800, rising by yearly increments of £50. Private practice to be allowed wherever expedient.

2. *Pension.*—After 15 years' service at the rate of £1 a day.

3. *Quarte* [illegible] cal quarters in accordance [illegible] ence.

4. *Messin* [illegible] organised mess should be established.

5. *Recognition* to be granted for any work outside medical duty.

6 —*A medical service* for the whole West Coast might be easily constituted whereby all might serve under the same conditions and one principal medical officer, &c.

This suggestion I have placed last, though it is really the most important, but one feels shy in throwing out practical hints lest there might be an epidemic of "fits" should this letter find its way to Downing-street. A system on these lines would be bound to attract young men of the right sort, for not only would the pay be adequate, but the chance of "seeing service" combined with pleasurable excitement would appeal strongly to the manly instincts of junior medicos. I apologise, Sirs, for taking up so much of your valuable space, but if you can succeed in improving a worthy branch of the service you will deserve the thanks of the community. I am, Sirs, yours faithfully,
Oct. 8th, 1900 M.D.

THE QUESTION OF THE COMMUNION CUP.

To the Editors of THE LANCET.

SIRS,—It is surely high time that some steps were taken to enlighten the general public on the dangers in connexion with the "one cup" mode of administering the Holy Sacrament. I have just lately heard from a lady friend who *says she knows of one church* at which a man with cancer of the tongue, and another suffering from some chronic throat affection (probably laryngeal phthisis) attend regularly the Communion Service and partake of the bread and wine. For myself I have long since given up going, for with my eyes open to its dangers and uncleanness I cannot bring myself to attend. Why cannot small glasses or cups be used, to be provided either by the church authorities (this I am pleased to hear some few churches have adopted) or by each communicant? This source of danger and means of communicating disease might easily be avoided Unobtrusively wiping the lip of the cup after each communicant has used it—also, I believe, done in some churches—is some improvement as regards cleanliness but is not altogether devoid of danger. It was a great comfort when, after much agitation, the Scotch form of taking the oath by uplifted hand took the place of "kissing the book" in courts of law. Why cannot the medical profession in these enlightened times also agitate over this more dangerous practice?

I am, Sirs, yours faithfully,
Oct. 7th, 1900 MEDICUS.

*** We refer to this question in another column.—ED. L.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Report of the Health Officer of Calcutta for 1899.—The Continued Rise in the Plague Mortality throughout India.—The Success of the Pasteur Institute at Kasauli.

MR. NIELD COOK in his report to the chairman of the Corporation of Calcutta refers to the drawbacks attending the system of having separate staffs from that of the Health Department for plague administration He draws attention to the unreliability of the mortality ratios and to the practically valueless information as regards mortality from special diseases The low birth-rate in Calcutta is probably due to the small female population It is interesting to note that the Christian population is the most prolific, then the Hindus, and lastly the Mohamedans, but it is admitted that the registration of births depending largely on the midwives is defective. The death rate for the year was 37 8 against 31·9, the average, the excess being fully accounted for by the plague. The mortality in the suburbs was higher than in the town. The infantile mortality was very high, giving a ratio of 366 8 to every 1000 children born during the year, the Mohamedan ratio being 504 3, the Hindu ratio 334 7, while the Christian was only 174 4. It is probable that the marriage customs largely account for these differences. The figures recorded appear to show that the female mortality was far heavier than amongst male, but there is no reason to explain this, and it is suggested that the female population is under-estimated Mr. Nield Cook's inquiries concerning the habitats of mosquitoes have been previously recorded He confirms previous observations that anopheles larvæ are not generally found in clean water, but that many of the anopheles tanks contained quantities of fish and tadpoles. On the other hand, they are not found in the filthiest tanks reeking with sewage. Cholera and small-pox were below the average of previous years. With regard to vaccination he records that 84·97 per cent. were successful. While the animal lymph gave over 95 per cent. results the humanised was only successful in 58·9 per cent. The protection from small-pox is not very satisfactory as the case-mortality among the vaccinated is recorded as 33 33 per cent., while among the unprotected it was 54·41 per cent. One of the numerous difficulties of the health officer of Calcutta is shown by the returns concerning the slaughter-houses. Mr. Nield Cook says: "The reason for the falling off in the number of animals slaughtered is that a great deal of slaughtering is done in unlicensed houses in the town which we are powerless to prevent, as the courts will not convict unless our officers have actually seen the animals slaughtered." Another consists in prosecuting for keeping animals for profit without a licence—the average fine being under Rs. 5. As Mr. Nield Cook says, "It paid better to keep a large number of cattle in an unlicensed and insanitary shed and adulterate the products than to spend money on well-constructed stalls, taking out a licence and selling only pure milk and ghee." In 1898 he also showed that the milk supplied was for the most part adulterated with sewage-contaminated water from shallow wells close to the sheds, and he now says that "no appreciable improvement has been effected." The conservancy troubles and difficulties in Calcutta are perennial and the insanitary state of the buildings appears hopeless. The report of one year on these subjects is very much like others. In the course of his report Mr. Nield Cook refers to several points upon which he has previously made suggestions but in which no change has been effected. It is hoped that with the new Act a better day is in store for Calcutta. The previous Commissioners were numerous and chiefly native but the present board is much smaller and has a larger European element. The disgraceful condition of the city is patent to the most casual observer. As the metropolis of India it is an unpleasant wonder to all new-comers.

The plague mortality continues to rise, especially in the Mysore State and the Bombay district. The total deaths in India last week were 1049, against 691 in the preceding seven days. Calcutta reports 78 deaths and Bombay city 52. The plague is slowly increasing in the city of Poona and the death-rate is more than treble the normal. Part of this, however, is due to cholera. Cholera still continues in the military cantonments and now enteric fever has broken out in an epidemic form amongst the European troops at Quetta. 17 deaths have so far occurred. It is still prevalent in Kashmir. At the present time plague seems to be quiescent in the cities of Calcutta and Bombay. The indications for a recrudescence must be carefully sought for. The present weekly minimum returns of plague deaths seem about the same for the two places, but in Calcutta suspicious deaths are included in the figures. An examination of the Calcutta returns brings out the following. After the decline of an outbreak and during the quiescent period (such as the present) the number of deaths returned as suspicious is about half the amount of the deaths from plague, but for a month or two before the active development of an outbreak such as occurred last spring the suspicious deaths rise so as to equal in number those from plague. With the rapid onset of the outbreak the deaths from plague increase in proportion so fast that during the worst stage they may exceed ten times the number of suspicious deaths. This comparison is not possible in the case of Bombay. All that can be inferred is that the number of deaths from plague is double that recorded The general mortality in Bombay is twice as great as its normal amount. Famine is rapidly decreasing, the numbers now on relief having sunk to less than 4,500,000.

The new Pasteur Institute has been quite busy. 26 out of the 39 patients who have been admitted since August 9th have completed the course of treatment. The effect has been quite normal in all cases. Five new cases, all natives, have entered during the week and 13 patients are now attending the institute. The Government can well afford to ignore the petitions and indignation meetings of a few energetic anti-vivisectionists.

Sept. 13th.

Mr. George Sanders, a former mayor of Taunton, has presented the Taunton District Nursing Association with a large house as a memorial to his wife.

THE PARIS CONGRESSES AND COLONIAL SANITATION.

(From our Special Correspondent.)

Forced Labour and Public Health.

The International Congress of Colonial Sociology which met in August and the International Peace Congress which has just concluded its sittings discussed colonial questions at great length and in doing so devoted some time to the consideration of measures calculated to protect and improve the health of the native populations. In such matters sociology is intimately connected with hygiene and it is difficult to draw a line of demarcation between the two. For instance, there is the question of the *corvée* or forced labour. In some French colonies this is allowed for a period of 30 days in the year; but it almost invariably gives rise to abuses and sometimes it has been prolonged illegally to 160 and even to 200 days. The natives, also, are frequently sent great distances from their homes, where both food and shelter are insufficiently provided, and what with exposure and hard work a very high death-rate results. In the face of the evidence adduced both congresses stigmatised, by the resolutions they adopted, the system of forced labour as a cause of the diminution of the native population and as likely to foment a spirit of revolt. The measures taken to prevent the abuse of the system are never efficacious, and, after all, good work is only done by willing workers. Nor is there, as a rule, a lack of willing workers where sufficient pay is offered. The principal advocates of the *corvée* are those who wish to have work done but do not wish to pay for it. Therefore, both congresses voted against the *corvée* system, and this not only as a measure of justice and humanity towards the natives or as a matter of policy to prevent disturbances and risings, but also as a sanitary necessity to check the high death-rate and the epidemics that accompany the application of the *corvée* system. What stood out prominently in the discussion of this and other questions was the mistrust felt in regard to colonial officials. Perhaps this mistrust is more justifiable with regard to the French than to the British colonies. Not that I would for a moment make any disparaging comparison between the two nations, but it is an undoubted fact that Frenchmen do not so readily expatriate themselves as Englishmen, consequently it often happens that a Frenchman only resigns himself to emigration when he has such a stain on his character that life at home becomes intolerable. The same may be said of some British emigrants, but the proportion of black sheep is not so great because many more Englishmen emigrate from choice and not from necessity. More particularly in Africa one of the greatest difficulties in dealing with the native tribes is their utter want of forethought—they live without the slightest care for the morrow. Then if there is a bad harvest, a flood, or any other untoward occurrence, great distress prevails, accompanied with much sickness and a high death-rate. Since 1893 societies have been started among the natives of Algeria so as to create funds for the purpose of granting loans for the purchase of seed and for help in sickness, &c. These sort of mutual benefit societies and agricultural banks have helped many natives to tide over an evil hour, thus contributing to maintain the prosperity and health of the colony, and the Congress of Colonial Sociology passed a resolution recommending that such institutions should be established wherever local circumstances seemed favourable to similar endeavours. When, however, this same proposal was brought before the Peace Congress as tending to the pacification of the populations concerned M. Laroche, who is an eminent authority on colonial questions, rose and protested Some measure of success, he said, might have been achieved in Algeria, but that was an old colony; it had been occupied by the French for 60 years and was only a few hours from Marseilles. In the more recently acquired and more distant colonies the European functionaries were not to be relied upon. Instead of teaching thrift they would utilise such institutions to practise still greater extortions and robberies upon the natives. So it comes to this—that whether the question be considered only from the sanitary or else from the general point *of view the first difficulty* and the first necessity is to obtain honest and reliable functionaries.

THE SANITARY MEASURES PROPOSED.

Needless to say, the alcohol and the opium traffic came in for a large share of abuse. Resolutions were passed urging that the agreement embodied in the Acts drawn up at Brussels in 1890 and 1899 so as to restrict the liquor trade in certain parts of Africa should be generalised and that by diplomatic agreement such restric- [illegible] he colonies where there was a [illegible] was urged that there should [illegible] r administrative department established in all colonies to deal with health questions as affecting the native populations. This would be, it was *affirmed, the most effective means of preventing* the physical degeneration of the natives. Unfortunately the tendency has been to study colonial sanitation only in so far as it affects the European troops and settlers; but it is now urged that the only moral justification for acquiring colonies is that the superior and conquering race shall confer on the natives greater security of existence and a higher moral and material standard of life. Thus at the International Congress of Hygiene the sixth section was devoted to military, naval, and colonial hygiene, but the papers read on the latter subject discussed the outfit to be given [illegible] expeditions, the filtration [illegible] ch the Europeans drink, [illegible] stations for the sick and [illegible] as said about the natives. [illegible] it very properly declared [illegible] with the technicalities of sanitation, enthusiastically re-affirmed and endorsed the resolution carried by the Congress of Colonial Sociology to the effect that sanitary-measures and reforms should not be limited to the European populations of the colonies. Good sanitation is as necessary for the natives as for the colonists and the Congress of Colonial Sociology by a series of resolutions indicated what measures of this description seemed most urgent. Firstly, they were in favour of segregation for cases of leprosy but proposed that the lepers should be placed within domains situated at considerable distances from towns and sufficiently large to enable the lepers to enjoy a fair amount of liberty within the [illegible] district. The public authorities should t[illegible] matter in hand and see that all that is ne[illegible] *provided. Lepers should also* be *registered* and *notices* sent to the local authorities whenever they changed their domicile. Then the Congress was very emphatic on the need of adopting effective measures to check the spread of syphilis among natives. It urged that more care should be taken to explain the nature and the dangers of this disease and to provide the necessary medical aid so that natives should have no difficulty in obtaining gratuitously efficient treatment. In those colonies where prostitution is placed under police and medical surveillance the best rather than the worst European methods and regulations should be imitated With regard to small-pox there should be public vaccination stations established in as many localities as possible for the benefit of the natives. Then wherever possible native schools of medicine should be created and, above all, it was considered urgent to train as midwives a large number of native women. After this complaints were made that in organising the scavenging and the drainage of towns in the colonies there was a tendency to neglect the native quarters though they really require more care and attention than the quarters inhabited by Europeans.

For [illegible] ployed and n[illegible] In a word, [illegible] ould be extenc[illegible] nly can [illegible] ous; and to appreciate [illegible] the natives should be [illegible] n Europe. Nor should all these measures be left to the colonists themselves, who, too often, are the worst enemies of the natives. There should be some method of inspection and control, either from the metropolis or at least from some large centre, so that the inspectors should be quite independent of all local interests and influences and able to act with impartiality.

Such were the desiderata of a large number of delegates who belong to various colonising nationalities and who have made a special study of all that relates to colonial expansion. There is little or nothing in this with which the sanitary reformer is likely to disagree, but its realisation will be a matter of great difficulty. Instead of emigrating with the fixed purpose of helping in every way to establish a well-administered and prosperous colony the emigrant is too often animated with the sole desire of making "his pile" rapidly and then returning home Hence the neglect and the abuses that are a discredit to Europeans, that cause insurrections, and too often result in both the moral and physical degradation of the natives. The Paris Exhibition, in bringing together from all parts of the world men who have personal experience of colonial life, has enabled them to place on record what should be done; and though there is nothing very novel in all these proposals, yet the fact that they have thus been authoritatively brought forward should be of use and should serve to stimulate the desire for colonial reform and for better administration. Above all, it is a wholesome sign to find that the natives have now met with a large amount of public attention. It is just as necessary to secure good sanitation for the natives in the colonies as to watch over the sanitary condition of the poor at home.

Paris, Oct. 8th.

MEDICAL TITLES IN GERMANY.

(FROM OUR BERLIN CORRESPONDENT.)

ENGLISH visitors to Germany are often surprised at the great number and variety of titles existing in that country. In ordinary conversation they hear the terms "Herr Geheimrath," "Frau Regierungsrath," &c., lavishly used, and they soon become aware that Germans in general are very fond of titles and attach a great importance to those distinctive appellations. A short article on German titles, and especially on such as are conferred on medical men, may therefore be not without interest to the readers of THE LANCET. But before entering on the subject I must explain that in the space at my disposal it would be impossible to do more than touch upon a small portion of the extensive question of German titles, for the regulations defining the rank and dignity conferred by the several [illegible] tremely elaborate and there are well- [illegible] usage in the various states of the [illegible] fact, but very few men who have a *complete* understanding of the subject, and they have only succeeded in this by m[illegible].

There are two points [illegible] German practices with respect [illegible] In the first place, a German who has received a title or an official position of any kind expects to be always addressed accordingly, not only in epistolary correspondence, but also in conversation. For instance, in speaking to a town councillor (Stadtrath) *whose* actual family name is Schmidt it is essential to call him only "Herr Stadtrath," and a letter intended for him must be addressed "Herrn Stadtrath Schmidt." Another peculiarity is that the wives of possessors of titles, officers, or public officials usually assume their husbands' titles, so that the wife of a colonel (Oberst) mus[illegible] addressed as "Frau Oberst." Some writers not of [illegible] have asserted [illegible] possessors of titles have a right to be addressed in a corresponding manner, so that the daughter of a Government councillor (Regierungsrath) ought to be "Fräulein Regierungsrath," but this is quite erroneous and a mere flight of fancy. Passing now to the strictly medical side of the question it must be explained that the proper official designation of a qualified practitioner is "Praktischer Arzt," but this title is only used in *communications of* the nature of letters and never in conversation. It would, in fact, be quite unusual in speaking to a medical man to say "Herr Arzt." The great majority of medical men having also taken the degree of M D. they are addressed in conversation as "Herr Doctor," this title being used indiscriminately by the public in speaking to every medical man although he may not be M.D. After having been in practice for a certain time, perhaps from 20 to 25 years, *medical men who are* of good professional standing and have not made themselves too prominent as opponents of the Government may, on the recommendation of the Minister, be favoured by the Sovereign with the title of "Sanitätsrath" (sanitary councillor). The usual procedure is that patients or friends of the medical man in question present a petition to the Government asking that he may be promoted to that honour. Sometimes the promotion is granted spontaneously for exceptional services to the town and the State and also on special occasions, such as a jubilee. On account of a rather high stamp duty being required for the diploma by the new Stamp Laws and also on account of a medical man so promoted having declined to pay this duty[1] the Minister of Public Instruction, as chief of the medical department, has ordered that medical men must beforehand declare expressly that they will accept their title. Medical men having this title are addressed in conversation as "Herr Sanitätsrath," the title of "Dr." being omitted, whilst on letters the proper address is "Herrn Sanitätsrath Dr. X." After a certain time the "Sanitätsrath" may be promoted to the rank of "Geheimer Sanitätsrath" (privy sanitary councillor). This title is used in the same way as "Sanitätsrath," but as the expression "Geheimer Sanitätsrath" is rather lengthy it is the custom in conversation to abbreviate it to "Herr Geheimrath," a word the dictionary rendering of which (privy councillor) is hardly a key to its practical application. On letters, *however*, the full *title must* be used. The same custom exists in the case of privy councillors of other classes as, for instance, privy councillors of justice, a title given to lawyers, or privy councillors of commerce, a title given to leading bankers, manufacturers, &c., who in conversation are addressed only in the abbreviated form, "Herr Geheimrath." Apart from the titles of "Sanitätsrath" and "Geheimer Sanitätsrath" there are other distinctions, the special features of which are that they are not given to medical practitioners merely as such, but are as a rule associated with a Government appointment. The chief medical officers of health of a district (Regierungsbezirk) and the members of the provincial medical boards when appointed to these offices receive at once the title of "Medicinalrath" (councillor). After a certain time passed in the Government service they are usually promoted to the rank of "Geheimer Medicinalrath" (medical privy councillor). The latter title belongs by virtue of their office to the members of the central medical department of the Government in Berlin, the senior members of this board enjoying even the title of "Geheimer Ober-Medicinalrath" (upper medical privy councillor). The title of "Geheimer Medicinalrath" is granted, moreover, as a mere personal distinction to the majority of ordinary professors of the universities and to the senior extraordinary professors as well. Professors who have received this distinction are addressed only as "Herr Geheimrath" in conversation, whilst the full title of Professor Virchow is "Herrn Geheimen Medicinalrath Professor Dr. Virchow." The highest distinction of this kind which can be conferred on anyone whomsoever is the title of "Wirklicher Geheimer Rath" (real privy councillor), which is very seldom granted to medical men, but is generally reserved for high Government and Court officials, Ambassadors, &c. A "Wirklicher Geheimer Rath" is addressed as "Excellenz" (your excellency), and the only medical man at present holding this title is Professor von Esmarch in Kiel. The term "wirklicher" (real) does not mean that the bearer has any duty to perform, the title being an honorary distinction only. The title of "professor" belonged originally to the occupants of chairs in the universities. There are ordinary and extraordinary professors, the number of the first category being strictly limited by the university statutes. Ordinary and extraordinary professors are first elected to that office by the faculty and the election has then to be sanctioned by the Sovereign.

Apart from members of the universities it became usual a few years ago to grant the title of professor to senior *privat-docenten* and also to the chief physicians and surgeons at some of the larger hospitals even though they had no connexion with a university. Whilst in the case of the members of the universities the term "professor" implies the performance of certain duties, the last-mentioned category receives the title of professor as a merely personal distinction conferred by the Government. The full title of a university professor of medicine would be in this form: "Ordentlicher [*or* ausserordentlicher] und öffentlicher Professor der Medicin" (ordinary [or extraordinary] public professor of medicine), whereas that of the second category is merely "professor" without any addition. In conversation, of course, no distinction is made, both categories being addressed as "Herr Professor."

What precedes relates only to the titles used in Prussia. The right to grant titles is a prerogative of the sovereigns of the individual states of the empire and the systems adopted by them differ widely from one another. In Bavaria, for instance, it is not usual to grant the title of "councillor" to ordinary practitioners, the title of "Hofrath" or "Geheimer Rath" (court councillor or privy councillor) being conferred only on medical men in the Government service or on the professors at the universities. The title of "Geheimer Hofrath" (privy court councillor) is used in Baden and in Wurtemberg. The title of "Sanitätsrath" used in Prussia and in several smaller states.

It is the rule to add the name of the state by which the title has been granted, for instance, Royal Prussian Medical Privy Councillor or Grand-ducal Baden Privy Court Councillor, &c. In the free cities of Hamburg, Lübeck, and Bremen no titles are conferred.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Medical Faculty of the University of Birmingham.

THE first session of the Medical Faculty of the University of Birmingham was opened on Oct. 1st by a conversazione held at the University at the invitation of the Vice-Chancellor and Council. Some 350 invitations were issued and the guests were received by Principal Lodge and the Dean of the Medical Faculty, Professor Windle. The Principal presided in the medical lecture-room and in the course of his remarks said that unity was the great principle to preach and divisions were scrupulously to be avoided. The University should be a corporate body banded together for the advancement and distribution of learning. The medical school was stated to be in a healthy and robust condition. The Dean then delivered an address on the advantages of the school and the system of training in the new University. This was listened to with much attention and interest. A vote of thanks was passed to the Dean, after which the Principal announced (amid applause) that the Council had that afternoon unanimously elected Professor Windle to represent the University on the General Medical Council.

The Clinical Board.

The prizes awarded by the Clinical Board were distributed on Oct. 8th in the lecture theatre of the General Hospital by Sir Henry Littlejohn, Professor of Forensic Medicine in the University of Edinburgh. At the invitation of the President, Mr. T. F. Chavasse, a large number of medical men and their friends assembled. Sir Henry Littlejohn dwelt upon the advantages of the practical side of professional education, stating that the system was due to the continental schools in the first instance, whose initiative had been wisely followed. Every department of medical study, with one exception, had its corresponding practical course, the exception being the important subject of medical jurisprudence. Every professor and lecturer of forensic medicine should in his opinion hold such an official connexion with the criminal authorities as would enable them to give a practical character to their prelections and thus to fit the students to give satisfactory evidence in the witness-box. He eulogised the Scottish system of medico-legal procedure which would ultimately, he thought, be adopted south of the Tweed. The small end of the wedge had been introduced by the establishment of the office of director of criminal prosecutions. Sir Henry Littlejohn proceeded to admonish the students present on various points of their professional training, his remarks meeting with hearty applause. A cordial vote of thanks was accorded to him for coming so long a distance to deliver the address and for the interesting and practical thoughts which it embodied.

The Musical Festival.

The triennial festival of music for which Birmingham has obtained so great a reputation concluded on Oct. 5th. The final meeting of the committee took place on the following morning when congratulations were interchanged on the splendid success which had been obtained. It was stated that the receipts amounted to £14,952, as against £13,722 for the previous festival, and that still there were many donations to come in. It is expected that a handsome sum

---

[1] THE LANCET, March 31st, 1900, p. 970.

will accrue
festival is always held.

Exhibition of Lunatics.

Much excitement has been created in the minds of a number of good people by the perusal of the syllabus of the medical faculty of the University, where it is stated that in the lectures which are delivered by the medical superintendent of the asylum as professor "cases will be exhibited." Science and sentiment have clashed in the correspondence upon the subject and, as usual, some misunderstanding is the result. The express sanction of the Asylum Committee is demanded as a matter of public interest. The chairman, however, has stated that so far no complaint relating to the present practice has been made to them either by the friends or the patients Therefore the committee cannot well take notice of anonymous correspondents on this subject. Probably more will be heard of this in the future.

Oct. 9th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Hospitals Fund.

A MEETING of the General Committee of the Manchester Hospital Sunday and Saturday Fund was held recently, when it was reported that the funds in hand, after deducting £552 for expenses, amounted to £6647. It was decided to make the following distribution to the medical charities:—

Royal Infirmary	£1129	Hospital for Consumption ..	£235
Children's Hospital	905	Cancer Pavilion and Home	112
Sick Poor and Private Nursing Institution ...	734	Hospital for Skin Diseases .	87
Salford Royal Hospital ...	576	Hulme Dispensary	66
Hospital for Incurables ...	503	Victoria Dental Hospital ...	55
Ancoats Hospital	462	Ear Hospital	41
Clinical Hospital...	424	Chorlton on-Medlock Dispensary	37
Royal Eye Hospital	406	Homœopathic Dispensary...	9
St. Mary's Hospital	396	Homœopathic Institution...	9
Southern and Maternity Hospital	356		

Last year the amount distributed was £7000. The decrease, no doubt, is due to the War Fund and Indian Famine Fund, to which the workers in many firms have contributed. The medical charities are to be asked to supply annually a uniform analysis of their accounts so as to facilitate the preparation of the statement on which distribution is based. A deputation from the committee of the Fund, from the Royal Infirmary, and from the Ancoats Hospital has recently urged on the Watch Committee the need of providing a horse ambulance service. The deputation were told that the matter was "under consideration"—where such matters often remain—but, what is more encouraging, they were also told "that their views would probably be fully met." It is by no means a new idea that Manchester suffers from want of a horse ambulance service, but while the Manchester corporation can speedily decide as to what must be done with hundreds of thousands, or even a million or two, a comparatively small matter such as a horse ambulance service to be used for the sick and injured requires an enormous amount of consideration and must not be determined on rashly.

Sale of Drink to Children.

Probably even the staunchest supporters of the view that moderate drinking is good for the individual and is good therefore for the community, and should not be interfered with by any legislative measures, would hesitate to include children in their conception of "the public" and would not be averse to a measure which would save them from becoming familiar with the manners and the language commonly to be observed at the licensed house at the corner. A conference to inaugurate a fresh effort in aid of a Bill to prohibit the sale of drink to children under the age of 16 years was held in the Botanical Gardens in connexion with the Band of Hope Union on Sept. 26th. There can be no question that fetching beer from the public-house, and often enough sipping it on the way home, are likely to bring about a habit which may, and in numerous cases will, result in the excessive drinking which is so injurious to the physical and moral condition of the people and which is so costly in its direct and indirect results as to be a heavy burden on the nation. It was stated by Mr. Wakeley, secretary to the Band of Hope Union, that "in Manchester children." There seemed to be a general feeling that no help was to be expected from the "politicians" in Parliament and that, as Archdeacon Wilson said, "the temperance party must give Parliament to understand that opposition was useless, for they were in earnest and would not be denied."

Death of Benjamin Jones Massiah, M.D. Edin., M.R.C.S. Eng.

It is with great regret that I record the death of Dr. B. J. Massiah of Didsbury, the scene of his practice for many years. His health had been failing for some months, and about three weeks ago he went to Bournemouth for change of air and rest On Sept 29th he became alarmingly ill and died on the 30th from peritonitis. Dr. Massiah studied at Bristol, his native city, and afterwards at Edinburgh. His first association with Manchester came from his appointment as resident medical officer to the Cheadle Convalescent Hospital In 1881 he began practice in Didsbury, where he took an active part in social and public life. His remains were cremated at the Manchester Crematorium. As life [illegible]

[illegible] friends. He married about 12 months ago and has left a widow to lament his death.

Fatal Maltreatment of an Imbecile.

An inquest was held on Oct. 5th, by Mr. Sidney Smelt, the city coroner, on the body of Francis Southgate, lately an inmate of the Manchester Union Workhouse at Crumpsall. Various witnesses deposed to having seen violence used towards the deceased by an attendant named George Pescott. Mr. W. J. Heslop, police-surgeon, said that there were marks on the neck of the deceased such as could be made by a towel twistened and tightened in the manner that had been described. The larynx had been fractured, and the cause of death was asphyxia. The jury returned a verdict of wilful murder against Pescott, and he was committed for trial at the next assizes on the coroner's warrant.

Oct. 9th

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The New Sanatorium at Delamere Forest for the Open air Treatment of Phthisis: the Foundation stone laid by the Earl of Derby, K.G.

THE foundation-stone of the new sanatorium which is being erected at Delamere Forest, near Frodsham, as an accessory to the Liverpool Hospital for Consumption, was laid on Oct. 6th by the Earl of Derby, in the presence of a large and influential gathering, which included Lady Willox and Mr. W P Hartley, who jointly contributed the munificent sum of £15,000 towards the projected undertaking. The buildings in course of erection will be of a description suited to the open-air treatment of phthisis. The main block will contain medical officers' rooms, matron's rooms, and small sitting-rooms for special cases, with accommodation on the first floor for a limited number of patients. Behind this block will be the dining-hall, to which there will be no means of approach except through the open air; and behind that will be the block containing the kitchens and servants' apartments, similarly approached. The bulk of the patients will be housed in small detached blocks containing four or six bedrooms each, with the requisite baths and other accessories. These small blocks will be dotted about the estate in such positions and numbers as may be required. Attached to the main block and to each of the smaller blocks will be verandahs with a south or south-west aspect, so as to afford opportunities for rest and shelter in small companies Each bedroom in the main block will communicate with a balcony upon which the patient's bed may be placed. The construction of the building will be of the simplest character. Fire places in the rooms will not be required, as the principle of the treatment will be to keep patients as far as possible in the same temperature. Every arrangement has been made to favour the free circulation of fresh air. Mouldings and irregularities of surface will be carefully eliminated to prevent the accumulation of dust. Electricity will be largely utilised in the working of the sanatorium A pure water-supply can be obtained from various sources, including the Vyrnwy main of the Liverpool Corporation. Lord Derby, in an interesting speech, lauded the liberality of Lady Willox and Mr. W. P. Hartley and expressed the conviction that however useful such hospitals might prove to be, the scourge of consumption was to be exterminated rather by disseminating knowledge among the people as to the conditions for securing immunity from its ravages.

The Western Poor-law Conference: Meeting at Southport: Pauperism and Lunacy.

The meeting of the Western Poor-law Conference at Southport on Sept. 28th was presided over by Sir John T. Hibbert who thanked the Mayor for his kindly welcome to the conference. The Chairman remarked on the diminution of the number of paupers in Lancashire and Cheshire as compared with other English counties. 48 years ago the pauperism in England and Wales was 62·7 per 1000, while it was now only 25 4 per 1000. The number of out-door paupers had decreased from 955 000 to 580,000; child pauperism had decreased from 24·8 to 7 3 per 1000; the number of widows receiving out-door relief had decreased from 3 2 to 1·2 per 1000, and adult able-bodied pauperism had decreased from 13·2 to 3 per 1000. In spite of all the attractions of Poor-law infirmaries and improved workhouses, in-door pauperism had not increased in the same ratio as the population. When they considered that the drink bill for last year stood at £162,000,000, it could be easily understood why they still had a large army of paupers to deal with. Sir John Hibbert advocated classification in workhouses as far as possible, making the places comfortable for the old people and giving them every consideration, but not making them more comfortable than they would be outside. He made these remarks in view of the great financial difficulties in the way of providing old-age pensions. In Lancashire there was a decrease of pauperism last year, as compared with the average of five years, of 2617. In Cheshire there was a decrease of 926 for the same period. In Lancashire there were 18·5 paupers per 1000 of the estimated population, and in Cheshire 19 8, whereas in London the rate was 27 6, and in the west Midlands 27·4 per 1000. As to lunacy they had an unpleasant and difficult question to deal with. During the year the number of insane paupers had increased from 95,462 to 96 865, following a continual increase for the past 12 years. He would not say that it was due to increased lunacy; it was due largely to the removal of pauper lunatics from workhouses and other places to asylums, encouraged by the 4*s.* a week allowance made to the guardians. So far as he could gather from the reports of superintendents of asylums the increased number of lunatics to be cared for was attributable to the lower death-rate in their asylums consequent on improved surroundings, the excessive use of alcohol, the stress and competition of the age, overcrowding, and a gross neglect of hygienic conditions among the lower classes. He thought the incurable yet, perfectly harmless, cases might be cared for and treated in a less costly manner than at present. Mr. Burns, chairman of the West Derby Board of Guardians, read an interesting paper on the Proper Use of Workhouse Infirmaries, in which he advocated separating the hospital from the main body of the building, even at a considerable distance He expressed his belief that the time was approaching when all hospitals established for the relief of the sick poor should be brought under the control of the State.

Medical Faculty, University College, Liverpool.

A commission in the Royal Army Medical Corps has been placed at the disposal of the above medical faculty by the War Office. I am informed that at the date of writing no application for the appointment had been received by the dean of the medical faculty.

Death of Mr. Charles Bowman Wilson, M.R.C.S. Eng., L M. Dub.

The lamented death of Mr C B. Wilson took place to day (Oct. 9th) at his residence, Abercrombie-square, at the age of 74 years. Mr. Wilson, who obtained the Membership of the Royal College of Surgeons of England in 1847, retired from the active practice of his profession about 15 years ago. Mr. Wilson was consulting surgeon to the Ladies' Charity and Lying-in Hospital and was formerly house surgeon at the old Liverpool Infirmary and vice president of the Liverpool Medical Institution. The deceased gentleman was held in great esteem by his professional *confrères*, to whom he had endeared himself by his genial and kindly disposition and by whom his demise is greatly deplored.

Oct. 9th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Opening of the New Pavilion in the Edinburgh Royal Infirmary.

IT is announced that H.R.H. Princess Henry of Battenberg has consented to open the new pavilion which has just been added to the Edinburgh Royal Infirmary in commemoration of Her Majesty's Diamond Jubilee. The date of the ceremony will probably be Oct. 26th.

Opening of the Winter Session in Edinburgh.

The winter session of the medical classes in Edinburgh will open on Tuesday, Oct. 16th. Judging from appearances it looks as if clinical medicine were to be at a considerable disadvantage during the approaching session. At the end of the summer session one of the pavilions on the medical side was closed for cleaning, repairing, and re-draining, the idea being that it would be ready for re-occupation in a month. It is not ready yet and no one seems to know when it will be. Unless this can be speedily rectified it will have a most hurtful effect upon the medical school as a whole.

Lecture Hours in Edinburgh.

Six well-known lecturers on the practice of physic whose lectures are recognised as qualifying for the University of Edinburgh have united in drawing the attention of the University Court to the unsuitable hour (2 P M.) which has been fixed for the lectures on the practice of physic during the coming winter session. They point out that the lecturers who have charge of wards in the Royal Infirmary and are engaged in the teaching of clinical medicine from 12 to 1.30 P.M. will not be at their best if required to lecture at 2 P.M., and, moreover, "it has been found that many students have great difficulty in giving their attention to any lecture at 2 o'clock." 9 A.M. is the lecture hour preferred by these gentlemen, so as not to interfere with the surgery and midwifery lectures.

The Glasgow Southern Medical Society.

The opening meeting of the Glasgow Southern Medical Society was held on Oct. 4th in the rooms of the Southern Medical Club, 18, South Portland street. The following office-bearers were elected. Honorary President, Sir Hector Clare Cameron. President: Dr. William Watson. Vice-Presidents: Dr. John Stewart and Dr. William McMillan. Treasurer: Dr. Andrew S. Tindal. Secretary: Dr. John Fraser Orr. Editorial Secretary: Dr. Andrew Wauchope. Seal-keeper: Dr. John Coulson Howie. Extra Members of Council: Dr. Alex. O. McArthur, Dr. Duncan Macgilvray, and Dr. Alexander Roxburgh. Court Medical: Dr. Hugh Kelly, Mr. Robert H. Pavey, Dr. James W. Allan, Dr. Alexander Rankin, and Dr. Robert W. Forrest. Representative to Victoria Infirmary: Dr. Charles E. Robertson.

Oct. 11th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Queen's Visit to Ireland.

THE Queen has sent the following reply to the address which was presented by the Royal College of Surgeons in Ireland on the occasion of her visit to Ireland:—"I thank you heartily for the loyal and dutiful address which you presented to me during my recent stay in Ireland. It gave me a particular pleasure to receive the representatives of your distinguished profession, the reputation of which for skill and devotion to duty has lately been so conspicuously maintained under the severest tests." The reply was sent to the President of the College by Sir Matthew White Ridley, the Home Secretary.

Meath Hospital and County of Dublin Infirmary.

The medical session will open at the Meath Hospital on

Convalescent Home for the Mater Misericordiæ Hospital, Dublin.

Beaumont, Drumcondra, has recently been purchased as a convalescent home in connexion with the Mater Misericordiæ Hospital The grounds, extending over 110 acres, give ample facilities for the exercise of convalescent patients, and the house, which commands beautiful views, affords at present accommodation for about 50 patients. It is proposed later to increase the size of the buildings.

Belfast Public Health Committee.

Dr. Henry O'Neill, J.P., who was appointed by the corporation of Belfast as a delegate to represent them at some recent congresses, has just presented to the Public Health Committee a report on the inspection and sterilisation of milk as conducted by several municipal corporations. After pointing out the diseases liable to be conveyed by milk and the effect of its sterilisation, and the causes of diarrhœa (as due to unsterilised cow's milk) leading to a high infantile mortality, Dr. O'Neill quotes Dr. F. D. Harris, who says that during the past five years of the children under six months old who have died in St. Helens from diarrhœa 81 per cent. were bottle fed. A very full account is given in Dr. O'Neill's report of the method employed at St. Helens, from Dr. Harris's recent paper read at the Ipswich meeting of the British Medical Association. He also mentions that it is proposed to erect a central sterilising milk station at Batignolles, near Paris, a point on the Great Western Railway of France where 43 per cent [illegible] the capital arrives. Dr. O'Neill [illegible] on "The Improvement of the [illegible] ter," and concludes a very interesting report by recommending that the Public Health Committee of Belfast should appoint a sub committee to consider the matter and to prepare such regulations as should enable those who may desire to do so to obtain an abundant supply of pure sterilised milk at small cost. He also suggests that two properly qualified female sub-sanitary officers should be appointed whose duties should be to visit and give instruction to persons who have the charge of infants regarding the proper feeding of children the birth of whom has been registered, to visit dirty houses and to endeavour to get the occupants to keep them clean, and to visit each house where a death from diarrhœa or enteritis has occurred and to investigate the cause of the death.

The Dietary Scale at the Belfast Workhouse.

The Infirmary Committee submitted their final report on the revision of the dietary scales in the Belfast Workhouse to the guardians at their weekly meeting on Oct 2nd. It is expected that £1000 a year will be saved by the scheme which was adopted. It has yet to be approved by the Local Government Board.

The Forster Green Hospital for Consumption, Belfast.

From a recent interim report it appears that the hospital is able to deal with 120 or 130 cases per annum and that while some patients contribute to their support the financial condition of the hospital leaves much to be desired. Considering the great prevalence of phthisis in Belfast this hospital is greatly needed and should be properly supported.

Royal Victoria Hospital, Belfast.

Dr. Henry O'Neill, J P, who has been on the surgical staff of the Royal Victoria Hospital for upwards of 20 years, has just resigned, owing to pressure of public and private duties. In addition to conducting a large practice Dr. O'Neill is a member of the Belfast City Council, and he has taken a great interest in questions of public health. He finds that his time is now so occupied that he is unable to give enough attention to hospital demands. If Dr. O'Neill devotes the additional time he will now have to the Public [illegible] to the city [illegible] high ideals [illegible] id his work, and while they all regret his resignation they hope the city council will benefit by the extra opportunities which he will now have of furthering public health reforms.

Oct. 9th.

(FROM OUR OWN CORRESPONDENT.)

The Last Sign of Life.

REFERENCE was made in THE LANCET of Sept. 29th (p 978) to Mr. Augustus D. Waller's method of ascertaining whether animal or vegetable tissues retained their vitality or not The material to be tested is connected with a galvanometer; in circuit with it is a source of electro-motive force (battery) to oppose the accidental electro-motive force (current of rest) of the matter tested. This electro-motive force is adjusted exactly so as to bring the galvanometer needle to zero A stimulus (e g, induction shock) is thrown into the material under test and if it is alive it responds by an electrical disturbance (current of action). For distinct reactions with objects having a low resistance (for example, a reaction above ·0 01 volt and a resistance less than 100,000 ohms) a galvanometer showing one-millionth of an ampère is sufficient. But for more delicate reactions with objects of high resistance (for example, a reaction below 0 001 volt, and a resistance above a megohm) a more sensitive galvanometer is indispensable. Mr. Waller ordinarily employs a Thomson's galvanometer with which one-ten-thousand-millionth of an ampère causes a deviation of five or six millimetres on a scale placed at a distance of two metres A four-way key is introduced for the convenience of cutting out the galvanometer when the stimulus is applied and for cutting in the galvanometer immediately afterwards to let it feel the current of action. Dead matter gives no current of action but may show common polarisation. This is distinguished by the direction, polarisation currents being inverse to the stimulus and currents of action being direct. The *electro-motive value of the reaction varies with the* nature of the object, the intensity of the excitation, and the time which has elapsed before the establishment of the galvanometric circuit It is ordinarily measured in hundredths and thousandths of volts; it is diminished more or less rapidly with the progressive extinction of vitality; it is entirely abolished by boiling.

Professional Secrecy.

It is becoming more and more difficult in France to lay down exactly what are the limits of professional secrecy, and all [illegible] different courts of [illegible] Hitherto the rul [illegible] ute and that nothing can dispense the medical man from the obligation, not even the permission or death of the patient. Despite this the Court of Appeal of Toulouse has just allowed a remarkable exception to this law, hitherto so strictly observed. The court gave judgment in a case involving the disposition of some property. One of the witnesses summoned was the medical attendant of the deceased who was also his personal friend. Counsel for the other side objected to the admission of the medical man's evidence as being a violation of professional secrecy. In opposition to this contention the court decided to admit the evidence as good, arguing that it contained two classes of facts—the one which had been obtained by the medical man in his capacity as friend, and which, therefore, had nothing to do with professional secrecy, the other which concerned the complaint of the deceased, which was a matter of public knowledge, for everyone in the district knew that he had died from morbus cordis, while the explanations furnished by the medical man with regard to the latter class of facts were necessary to allow him to justify certain matters as to which sundry witnesses had brought charges against him This unexpected judgment provoked some very fair and just criticism on the part of Dr. Maurans, an expert in the matter, writing in the *Semaine Médicale* Mar [illegible] same time both the [illegible] their patients, personal friends [illegible] en confidences and it is very [illegible] given to the f. [illegible] l adviser, and in order to avoid the danger of a medical man being charged with violation of professional secrecy it is much better to keep absolute silence. It is extraordinary also to see the Court of Toulouse laying down that, because the illness from which a patient is suffering is universally known, therefore his medical attendant is dispensed from the obligation of secrecy. Many medical men have been found guilty by different courts for having made known the nature medical attendance and drugs to everyone in the colony of Victoria would require 550 medical men and 130 dispensing chemists and would cost the State £300,000—or on an average 18*s.* 6*d.* per adult male in taxation. Under the arrangements of the friendly societies the average cost per member would be 24*s.* 6*d.* per head.

Dinner to Sir Thomas FitzGerald.

On August 16th about 80 members of the medical profession in Victoria entertained Sir Thomas FitzGerald at dinner on his return from South Africa where he had been serving as consulting surgeon with the Imperial Army Medical Corps. His Excellency the Acting Governor presided and proposed the health of Sir Thomas FitzGerald in a highly eulogistic speech. In replying Sir Thomas FitzGerald said that he had been struck with the very friendly relations which prevailed between the civilian and army surgeons; and with reference to the arrangements he could not understand Mr. Burdett-Coutts's charges. Everywhere he went he found the arrangements admirable.

A Medical Man Convicted of Procuring Abortion.

Mr. Michael Lyons Butler was charged at the Central Criminal Court with having used unlawful means to procure abortion, was found guilty, and was sentenced to five years' penal servitude.

Sept. 1st.

Obituary.

ROBERT STRAFFORD SMITH, M.D. R.U.I.

THE utmost sorrow was felt in Belfast on Friday morning, Oct. 5th, when it was announced that one of the most promising of the younger physicians of that city had died. Since the spring of the present year Dr. Smith had been suffering from recurring attacks of carbuncles of the neck which greatly lowered his strength. Under careful surgical treatment these had been got rid of, but about two weeks ago, after having been out at his work, he was obliged to return to bed with an obscure feverish attack and pains in the left leg simulating sciatica. Afterwards the pain extended to the other leg, and a careful examination of the blood in the laboratory of Queen's College showed no signs of any enteric mischief (absence of Widal's reaction) but an extraordinarily increased leucocytosis (60,000 leucocytes in a cubic millimetre), establishing the very serious diagnosis of septicæmia. Then the nervous system became involved, and, finally, evidences of septic pneumonia appeared. On Thursday night (Oct. 4th) he became unconscious and passed away on the following forenoon. The eldest son of a most distinguished physician (Dr. J. W. T. Smith, who died 10 years ago and who had an enormous consulting practice in the north of Ireland), Dr. Strafford Smith was educated at Queen's College, Belfast, and he graduated M.D. of the Royal University in 1882. He afterwards visited London and Vienna. Commencing practice in Belfast in 1885 he was first attached to the Ulster Hospital for Women and Children, but subsequently he joined the staff of the Royal Victoria Hospital where he was one of the physicians and also secretary of the medical and surgical staff On the death of Professor Cuming he was appointed Lord Chancellor's Visitor in Lunacy. Dr. Smith was greatly liked both for his professional abilities and for his kind and sociable disposition. His death is particularly sad from the circumstance that he had been married only 18 months, and the greatest sympathy is felt for his widow who with a little son is left to deplore his premature death. The funeral took place on Sunday afternoon, when there was a large number of the members of the medical profession present to show a last token of respect. Unfortunately, owing to the University examinations in Dublin, several of the professors of Queen's College were unable to attend.

ALEXANDER STEVENSON, M.B., C.M. GLASG.

DR. STEVENSON of Ogle-terrace, South Shields, where he practised in partnership with Dr. James Drummond, died in Glasgow on Sept. 3rd after a short illness. Taken away at the early age of 31 years, almost at the commencement of what seemed a very promising career, he will be long remembered by his many friends as an earnest, skilful, and patient practitioner and an upright Christian man. His first start in life was in a lawyer's office, where he spent a year or two, and then turned his thoughts to the medical profession. He accordingly proceeded to the University of Glasgow, where he proved himself a diligent student and graduated with commendation as M.B. and C.M. in 1895. Dr. Stevenson spared no pains in qualifying himself for the practical work of his profession. He was never idle and in his native town of Dumbarton he was well known as a temperance advocate and religious worker. He has left a widow and one child.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examination the following candidates passed in the subjects indicated:—

PART I.

Chemistry.—A. Bernfeld, Royal Free Hospital; A. G. Elsworthy, Charing-cross Hospital; M. S. Jevons; R. Khedkar, Bombay; and R. H. Rigby, Leeds.

Materia Medica and Pharmacy.—J. B. Bradley, Birmingham; E. C Curtis, Aberdeen; A. T. Greenhill, St. Bartholomew's Hospital, T. E. Johnson, London Hospital; R. Khedkar, Bombay; C Millauro, Westminster Hospital; and J. M. Worswick, Manchester.

PART II.

Anatomy.—H. Archer, Leeds; St. C. G. Ballenden, Birmingham; H. A. S. Gover, St. Mary's Hospital; R. V. Khedkar, Bombay; F. C. R. M. Knight, Guy's Hospital; W. Lovell, St. Mary's Hospital; E. H. McMahon, Charing-cross Hospital; H. P. Margetts, St Bartholomew's Hospital; S. Northwoc [illegible] Pegler, Leeds; A. C. Stark, Westminster [illegible] Manchester; R W. Taylor, Leeds; M. L [illegible] pital; M. G. L. Walker, Leeds; and S. H. [illegible] Hospital.

Physiology.—G. H. Almond, Cambridge; H. Archer, Westminster Hospital; St. C. G. Ballenden, Birmingham; E. W. C. Bradfield, St. Mary's Hospital; W. L. Crabtree, Leeds; H. A. S. Gover, St. Mary's Hospital; I. Griffith, London Hospital; A. F. Heald, Cambridge; H. S. Jones, Guy's Hospital; R. V. Khedkar, Bombay; F. C. R. M. Knight, Guy's Hospital; W. Lovell, St. Mary's Hospital; H. E Scoones, St. Bartholomew's Hospital; C. M. Scott, Royal Free Hospital; J. B. Stephens, St. Mary's Hospital; M. L Tyler, Royal Free Hospital; and M. G. L. Walker, Leeds.

UNIVERSITY OF GLASGOW.—The following candidates have passed the first professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (B., botany; Z., zoology; P., physics; C., chemistry):—

Andrew Blair Aitken (B., P.), William Smith Allan (B., Z.), Andrew Allison (B., P.), Andrew Woodroffe Anderson (B., P.), Donald Arbuckle (P.), Robert James Arthur (B., Z.), John Bain (C.), Hugh Barr (B), Allan Robertson Barrowman (B., P.), Archibald Grainger Bisset (B). Charles Brown (P.), John Brown (C.), George Yuille Caldwell (B.), John Paterson Carmichael (Z.), Peter Carrick (B., Z.), Robert Buchanan Carslaw, M.A. (P., C), William Smith Craig (C.), Robert Wilson Dale (B., P.), Thomas Thornton Macklin Dishington (Z, C.), Allan Campbell Douglas (B., P.), Charles Milligan Drew (B., Z., C.), Walter Duffy (B.), John Shaw Dunn (B, P.), John Ferguson (B., Z., P., C.), Charles Conway Fitzgerald (Z., C), Edward John Fitzgerald (Z., C.), Hugh Harvey Fulton (B., P.), William Gilchrist (C.). William Harold Gillatt (P.), Joseph Glaister (B), James Glover (P., C.), Alexander Graham (B, P.), David Livingstone Graham (B., P.), Donald John Gollan Grant (B, P.), Alexander Robertson Forrest Hay (B., Z., P.), James Waugh Hay (B, Z.), John Cochrane Henderson (Z., P., C.), Lawrence Hislop (B.), Ralph Howell (B., Z), Alexander Hunter (C.), James Hunter (B., P.), Archibald Yuill Hutchison (B., Z., P., C.), Harry Stewart Hutchison (B., P.), Alexander Jamieson (B., C), Arnold Ernest Jones (B, P.), Douglas Robertson Kerr (B., Z.), James R [illegible] Notman Kirkwood (Z., C.), Robert Wrig [illegible] cAulay (B., Z., P., C.), Ernest Bowman [illegible] Iacaulay (B., P.), Donald [illegible] Glaister M'Cutcheon (B., C.), John Finlay [illegible] 'Dougall (C.), James Boston M'Ewan (C), [illegible] (B., P.), Duncan Macfadyen (B., P.), John M'Farlane (B., P.), Robert Macfarlane (B., P.), Alexander Stuart Murray Macgregor (B. P.), Milne M'Intyre (B, C), Charles Gordon Mackay (B., C.), David James M'Leish (B, Z., P.), Norman Alexander Macleod (P.), [illegible] Alexander Stewart M'Millan (P.), Matthew [illegible] M'Murrich (B, P.), Norman Smith [illegible] Richard Cameron Macpherson (B., C.), William Main (P., C.), James Marshall (Z., C.), William Blair Morton Martin (B, P.), Andrew Meek (B., P.), John Moffatt (P., C.), William Struthers Moore (Z., C.), Gavin Denholme Muir (P.), John Muir (Z., C.), Macdonald Munro (B), Frank Anderson Murray (B), George Clement Nielson (B., P.), Thomas Orr (B., Z., P.), Howard Henderson Patrick (B., P.), Arthur Geoghegan Paxton (Z., C.), John Pearson (B., P.), John Clegg Pickup (B., Z.), Andrew Maclean Pollock (B, P.), Henry Sherwood Ranken (B., P.), Donald Ronald Reid (B, P.), Daniel Falconer Riddell, M.A. (Z., C.), Daniel Stevenson Richmond (P., C.), James Watson Richmond (C.), Alexander Robertson (B., P.), Berkeley Hope Robertson (C.), William Rolland (B., P.), John Macdonald Ross (P., C.), Edward Louis Sieger (P.), Robert Wilfred Simpson (P., Z), Alexander Hunter Sinclair (Z), Morrison Wood Smith (B., P.), James Alexander Somerville [illegible] ald Stewart (B.), William Stewar [illegible]), William Templeton (Z., C.), [illegible] Alexander M'Millan Watson (P [illegible] Archibald

Crombie West (B., P.)
Shanks Alexander (Z
Campbell (B., Z.),
[illegible]

The following candidates have passed the second professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch B.) in the subjects indicated (A., anatomy; P., physiology; M., materia medica and therapeutics):—

William
Banks (
Campbe
William
(P., M.),
William
Kirk (A.
Lovett
Macinty
M'Kenz
(A., P.)
Martyn,
Robert Clemens James Schlomka
(M.), Malcolm Bernard Gathorne
Smith (M.), Robert Cassels Smith
M.), John Barbour Stewart (P.),
n Allan Thom (A., P., M.), John
Hesten Thomas, (A., M.), William Wagner Turner (A., P., M.),
Robert Wallace (P.) Thomas Irby Wallace (P., M.), Robert
Watson (M.) Alexander Brown Watt (M.) Peter Millar Waugh
(A.), Robert Tait
Joseph White
(M.), Watson Yo
(A., P.), Jane Ca
Macleod Lochhea
Wallace (P., M.).

The following candidates have passed the third professional examination
(M.B.) and Bachelor
indicated (P., pathol y;
public health):—

John Anderson
Stoddart Barr
Cameron (M.),
David Beattie
Hugh Grant
rrar (P., M.)
George
n Fletcher (P.), William
Gemmill
David Kyle, M.A. (M.),
Alexande
a Lochrane (M.) Joseph
Paterson
M'Glashan (P.), Hugh
Archibald
M'Gaw M'Millan (P., M.),
Allan Dixon Mitchell (P., M.), Samuel
P., M.), Janet Thomson
Agnes Binkier Sloan

At the recent professional examinations for the degrees of M.B., Ch.B., the following candidates passed with distinction in the subjects indicated:—

A MEDICAL PRACTITIONER STRUCK BY LIGHTNING.—The *Maryland Medical Journal* mentions that on August 13th Dr W. H. Ravenscroft of Oakland, Garrett County, Maryland, was struck by lightning and rendered unconscious. His horse was stunned at the same time.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.—The following scholarships have been awarded: Entrance Scholarship, £30, to Miss J. Coupland; St. Dunstan Scholarship, value £60, to Miss Nora Smith.

ICE-CREAM.—The borough analyst of Plymouth having reported to the sanitary committee of that town in reference to the ice-cream sold in the streets, the sanitary committee has decided that premises where ice cream is manufactured shall be registered and supervised by the sanitary authority.

SURGEONS AND JURIES. — The
shire) bench of magistrates on Sept. 25th,
lists for the district, struck off the name
Royal College of Veterinary Surgeons,
embers of that profession should be

T BATH.—At the meeting of the
rdians held on Oct. 3rd it was reported
eight months of this year there had been
these children 658 had been success-
cases were postponed, 67 had exemption
had died.

firmary, as had been suggested. After a discussion it was eventually decided to erect a new building.

MEDICAL STUDENTS IN ITALY.—According to the *Supplemento al Policlinico* of Sept. 15th, during the last academical year the medical and surgical faculties of the Italian universities were attended by 6648 students distributed as follows 2009 in Naples, 783 in Turin, 530 in Rome, 504 in Bologna, 496 in Pavia, 358 in Genoa, 309 in Padua, 270 in Palermo, 260 in Florence, 218 in Pisa, 152 in Modena, 167 in Catania, 175 in Parma, 128 in Messina, 81 in Siena, 75 in Cagliari, 54 in Sassari, 35 in Camerino, 29 in Perugia, and 15 in Ferrara.

SANITARY CONDITION OF DARTMOUTH.—At the meeting of the Dartmouth Town Council held on Oct. 2nd Mr. J. H. Harris, the medical officer of health, reported that the inspector of the Local Government Board had visited the town relative to the arrangements made to cope with an outbreak of plague. He added that there was no isolation hospital belonging to the council nor were there arrangements for disinfecting Mr Harris also complained of the scarcity of water. The report was eventually referred to a committee.

ATTEMPTED MURDER OF A MEDICAL MAN.—On Oct. 8th a murderous attack was made on Dr. Julius St. Thomas Clarke of Leicester. His assailant was a man named Kirby who fired four shots at him with a revolver as he was walking near Nelson-street. One of the bullets lodged in the lower part of Dr. Clarke's spine, but has not yet been extracted, and the patient's condition is unfortunately very serious Kirby, who was immediately arrested and disarmed, has been in an asylum and is supposed to be insane A later report has been received to the effect that Dr. Clarke's general condition is much more satisfactory.

LEICESTER INFIRMARY BOARD.—The quarterly meeting of the board of governors of the Leicester Infirmary was recently held at the institution, Mr. T. Fielding Johnson presiding. In presenting the usual financial statement the chairman said that there was a balance due to the treasurer on the joint account of the infirmary, fever-house, and children's hospital of £668 4*s* 3*d* At the commencement of the year the infirmary was indebted to the treasurer in the sum of £2195 and at the close of the last quarter this sum had increased to £4826, but thanks to the timely legacies of the late Miss Dalton this large deficit had been nearly wiped off, and it was hoped that by the collections in the churches and chapels, the workpeople's donations, and receipts from other sources, there would be a balance on the right side at the end of the year. Owing to the large increase in the number of operations it had been decided that a new operating theatre must be built which would involve an expenditure of from £7000 to £8000. The report was adopted.

Medical Magistrate.—Mr. M. Cursham Corner, L.S.A., of Mile End-road, E., has been appointed a Justice of the Peace for the County of London, Tower Division.

The East Suffolk Hospital, Ipswich.—Dr. W. A. Elliston, President of the British Medical Association, and Mr. B. Edwards have resigned their appointments on the honorary medical staff of the hospital. At an election held to fill the vacancies Dr. T. Warner and Dr. F. Ward were elected.

The Poplar and Stepney Sick Asylum District.—A conference upon the Open-air Treatment of Phthisis will be held at St. Martin's Town Hall at 3 P.M. on Monday next, Oct. 15th, under the auspices of the managers of the Poplar and Stepney Sick Asylum District.

Literary Intelligence.—Messrs. Smith, Elder, and Co. announce a second edition in the press of the late E. J. Chance's "Bodily Deformities," Vol. I., brought up to date by John Poland, F.R.C.S. Eng. The hitherto unpublished Vol. II. on "Treatment," by the same author, will also be edited by Mr. Poland.—Messrs. W. B. Saunders and Co., medical publishers, Philadelphia, are opening a London Branch of their business at 161, Strand, W.C., for the sale of their medical publications in Great Britain and the Colonies.—Mr. Frederick Treves has written an account of his experiences in South Africa during the three months that the field hospital followed the relief column from Frere to Ladysmith. The record is based on notes written from day to day on the spot. The work, which is illustrated by a number of photographs, will be issued shortly by Messrs. Cassell and Co. under the title of "The Tale of a Field Hospital."

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Allardice, W. C., M.D. Glasg., has been appointed Certifying Surgeon under the Factory Acts for the Borough of Newcastle-under-Lyme, the Civil Parishes of Chesterton, Silverdale, Keel, and Madeley in the County of Stafford.

Anderton, W. B., M.B. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Second Resident Assistant Medical Officer to the Crumpsall Workhouse, Township of Manchester.

Ashby, A., M.B. Lond., F.R.C.S. Eng., has been re-appointed Medical Officer of Health by the Reading Town Council.

Birchall, E. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Assistant Medical Officer to the Walton Workhouse, West Derby.

Blaker, Percy S., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to the East London Hospital for Children and Dispensary for Women, Shadwell, E., vice Joseph Shardlow, resigned.

Body, Henry Martyn, M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health by the Crediton (Devon) Rural District Council.

Browne, Geo., M.D., M.Ch. Irel., has been appointed Certifying Surgeon under the Factory Acts for the Ballynahinch District of County Down.

Brown, J. Percival, M.B., Ch.B. Vict., has been appointed Junior House Surgeon to the Macclesfield General Infirmary.

Brown, John, M.D., D.P.H. Vict., has been re-appointed Medical Officer of Health for the Borough of Bacup.

Craig, John, M.B., Ch.B. Edin., has been appointed House Surgeon to the Dumfries and Galloway Royal Infirmary.

Dawson, W. E., L.R.C.P. Irel., L.S.A., L.M., has been appointed Resident Medical Officer, Tower Hamlets Dispensary, Stepney, E.

Evatt, John E., M.B., B.S. Durh., has been appointed Demonstrator and Assistant Lecturer of Anatomy at the University College, Cardiff.

Fisher, Charles, M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to the Victoria Hospital for Children, Chelsea.

Gemmell, Samson, M.D. Glasg., F.F.P.S. Glasg., has been appointed Professor of Clinical Medicine, University of Glasgow, vice McCall Anderson.

Hall, J. Basil, M.C. Cantab., has been appointed Honorary Assistant Surgeon to the Bradford Royal Infirmary.

Harding, R., L.R.C.P. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer of Health by the Kington Rural District Council.

Kingsford, Leslie, M.R.C.S., L.R.C.P., has been appointed Medical Officer to the Casualty Department of the East London Hospital for Children and Dispensary for Women, Shadwell, E., vice Percy S. Blaker, resigned.

Laurie, Langworthy, has been appointed House Surgeon to the Victoria Hospital, Bournemouth.

Macrae, D. Mackenzie, M.B. Glasg., has been appointed Resident Surgeon to the Wilts County Asylum, Devizes.

Mapleton, Henry Banbury, M.A. Oxon., M.D., C.M. Edin., D.P.H. Lond., has been appointed Medical Officer of Health for Newton Abbot, Devon, vice Harvey, resigned.

Mules, P. H., M.D. Edin., M.R.C.S., has [illegible] Surgeon to the Wrexham Infirmary, vi[illegible]

Pearce, D. A. C., M.D. Lond., B.S., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer of the Bridge Union, vice L. A. Winter, resigned.

Plumley, Arthur George Grant, M.B. Lond., M.R.C.S., L.R.C.P., L.D.S. Eng., has been appointed Dental Surgeon to the Clayton Hospital and Wakefield General Dispensary.

Rubra, H. H., M.D. Brux., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Anæsthetist to the Great Northern Central Hospital, Holloway-road, N.

Scofield, H. C. L., M.B., C.M. Edin., B.Sc., has been appointed Medical Officer to the Children's Home, Peckham Rye, S.E.

Sissons, A. T., M.B., B.Ch. Vict., has been appointed First Resident Assistant Medical Officer to the Crumpsall Workhouse, Township of Manchester.

Slater, B. H., M.B. Camb., M.R.C.S., L.R.C.P., has been appointed Honorary Assistant Surgeon to the Bradford Royal Infirmary.

Sturdy, H. Carlile, M.B. Durh., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the East London Hospital for Children and Dispensary for Women, Shadwell, E., vice S. Vere Pearson, resigned.

Thompson, William, has been appointed Public Analyst for the Borough of Stockport.

Wallace, J. Sim, M.D., B.Sc., L.D.S., has been appointed Assistant Dental Surgeon to the National Dental Hospital, London, W.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Bath Eastern Dispensary.—Resident Medical Officer. Salary £130 per annum, with furnished apartments, coals, gas, and domestic attendance.

Bradford Royal Infirmary.—House Physician for 12 months, unmarried. Salary £100 per annum, with board and residence.

Bristol City Hospitals.—Resident Medical Officer for the Ham-green Fever Hospital, Bristol, for one year. Salary £100 per annum, with board, lodging, and washing.

Central London Ophthalmic Hospital, Gray's Inn-road, W.C.—House Surgeon. Salary £50 per annum, with board and residence in the hospital.

Cheltenham General Hospital.—House Surgeon for two years, unmarried. Salary £80 per annum, with board and apartments.

Children's Hospital, Nottingham, St. Peter's Church Walk, Nottingham.—House Surgeon (non-resident) for six months. Salary at the rate of £100 per annum.

City of London Asylum, near Dartford, Kent.—Second Assistant Medical Officer and Pathologist, unmarried. Salary £150 a year, with board (except liquors), furnished apartments, washing, and attendance. Apply to the Clerk to the Visiting Committee, Guildhall, London, E.C.

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising to £150 by £10 annually, with board, furnished apartments, &c.

Corporation of Birmingham City Fever Hospital, Lodge-road.—Second Assistant Medical Officer. Salary £120 per annum, with board, residence, &c.

County Asylum, Lancaster.—Assistant Medical Officer. Commencing salary £125 per annum with the usual allowances.

County Borough of Croydon, Croydon Borough Hospital.—Resident Medical Officer for the Croydon Borough Hospital for Infectious Diseases, for one year. Salary £120 per annum, rising to £140 at the end of six months, with board and residence.

Derby County Asylum.—Second Assistant Medical Officer. Salary commencing at £110 per annum, rising to £130, with board, lodging, and washing. Apply to Medical Superintendent, County Asylum, Mickleover, Derby.

Devonshire Hospital, Buxton, Derbyshire.—Assistant House Surgeon. Salary £50 per annum, with furnished apartments, board, and washing.

French Hospital and Dispensary, 172, Shaftesbury-avenue, London.—Resident Medical Officer (not a female), speaking French, unmarried. Salary £80 a year, with full board.

Glasgow Corporation, Police Department.—Assistant to the Bacteriologist in connexion with the Health Department of the City for six months. Salary at the rate of 3 guineas per week. Apply to the Clerk of the Corporation Police Department, City Chambers, Glasgow.

Hull City and County Lunatic Asylum.—Second Assistant Medical Officer for the Asylum at Willerby. Salary £150 per annum, with board, apartments, and washing. Apply to the Town Clerk, Town Hall, Hull.

Hulme Dispensary (not Provident), Dale-street, Stretford-road, Manchester.—House Surgeon. Salary £150 a year, with apartments, attendance, coal, and gas.

Jarvis' Charity, Staunton-on-Wye, Hereford.—Medical Officer, to reside in house provided with garden and good stabling rent free. Salary £150 per annum and certain allowances. Apply to the Correspondent, Bredwardine Vicarage, Hereford.

Leicester Infirmary.—House Surgeon. Salary £120, rising £10 annually until the third year. Board, apartments, and washing provided.

London Temperance Hospital, Hampstead-road, N.W.—Assistant Resident Medical Officer for six months. Board and residence in the hospital and washing provided, and an honorarium given at the rate of 50 guineas per annum.

Northern Division of South Uist.—Medical Officer. Salary £77 10s. Apply to Mr T. Wilson, Solicitor, Lochmaddy, Clerk.

Paddington-green Children's Hospital, London.—Surgeon to Out-patients. Candidates must be F.R.C.S.

Kyleakin, Skye. [illegible] London —

[illegible] annum, [illegible]

DEATHS.

LOWSLEY.—On Oct. 4th, at Eldon square, Reading, Oded Lowsley, [illegible] year.

[illegible] residence, 88, Finchley-road, South [illegible] Milson, M.D., only son of the late [illegible], of Swineshead, Lincolnshire, in his 63rd year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

SECRET COMMISSIONS AND THE MEDICAL PROFESSION.

WE have upon previous occasions expressed our opinion that the outcry against secret commissions in the medical profession was greatly exaggerated. There can be no doubt that they are offered but even the offering is somewhat rare However, a particularly flagrant [illegible] its [illegible]"

"PRIVATE.—An Honorarium of Five per cent will be paid to Medical gentlemen on completion of all successful business introduced by them.

237, EARLSFIELD ROAD, S.W.

DEAR SIR,

Permit us to call your attention to the enclosed Circular.

The *Curative properties of the Thermal Springs of New Zealand* are comparatively unknown in England. All the facts contained in the Circular are based on Dr. Ginder's and other Medical Officers' Report to the N. Z Government, which will be found in detail, with analysis of the Springs, in the Official Year Book of the New Zealand Government for 1899 and previous years; the London publishers are Messrs Eyre and Spottiswood

We trust this communication will receive your approval and commendation

Your Obedient Servants,

J. BASTOW & SON."

We should like to point out to the New Zealand Government that if it wishes to exploit the Springs, as no doubt it does wish and has every right to do, this is the very worst way to set about it.

A POINT OF ETIQUETTE.

To the Editors of THE LANCET.

SIRS,—I have been giving first-aid lectures to the local fire-brigade in accordance with Fire Brigade Union This union confers the Red Cross badge on those surgeons who deliver three different courses of lectures to as many fire-brigades To complete the series and secure the badge I must deliver lectures to brigades to two of my opponent's fire-brigades. What course am I to adopt? The firemen will have to come over to this village for each lecture.—I am, Sirs, yours faithfully,

Oct 9th, 1900. VERITAS

*** If we understand "Veritas's" letter it would seem that his "opponents" (does he mean his brother practitioners?) will require his fire-brigades as audiences before they can obtain their badges, in which case they will not be likely to object to "Veritas" lecturing to their fire-brigades that he may obtain his badge "Veritas" is advised to communicate with his "opponents" and ascertain their views —ED L.

A CONFLICT OF EVIDENCE

AT Cardiff Police Court on Oct. 2nd, Dr. Frederick W. Evans of Charles-street was summoned for furious driving on the information of two police constables who stated that on Sept 26th they saw him driving along Cathedral road at a rate of about 13 or 14 miles an hour. The evidence of Dr. Evans and his coachman was to the effect that the pace hardly, if at all, exceeded 10 miles an hour, and their estimate would in the opinion of persons accustomed to horses be entitled to some weight From the constant use of the gig which is such a feature in the country practitioner's daily work he is likely to be a better judge of distance and speed than a city policeman. The magistrates however preferred the police evidence and fined Dr. Evans 10s.

"MOTOR CARS FOR MEDICAL MEN."

To the Editors of THE LANCET.

SIRS,—The gist of Mr Hirsch's experience with a motor-car is embodied in the last three lines of his letter in THE LANCET of Oct. 6th, p 1043 "Motor cars are certainly very useful but liable to get out of order, and I question whether I would buy one again with my present experience" Just so, and I would advise medical men to ponder well before purchasing a machine, costly as well as uncertain. To a medical man time and punctuality are both of value, and it is no joke to "jack up" at a critical moment, for there is always the glorious uncertainty of never knowing whether you will have to leave your car at some road side inn and get home by rail or be towed home or not. Just at the present time there has been a "boom" in car buying by a public ignorant of the intricate machine they are investing in and only waking up after possession to disappointment. There are many who suppose the only thing you have to do is to jump up, turn on a cock, and off you go? Far from it, you must be prepared for ever-recurring breakdowns I have joined an automobile club in the town in which I reside and have during the past six months had many opportunities of noting the capers of motor cars of various kinds and I find too many patients in hospital to please me I am now an on looker and patiently waiting events. Perhaps I may be told I may wait till my coffin is ordered, like the man who in the old days waited for improvement in bicycles, but to "dabble" in motor-cars requires a deeper pocket than bicyoles and all doctors are not rich. One great element of failure in my opinion is the rage for excessive speed. By a medical man whose work is mixed country and town the first question asked should be not "how fast will it go," but "how slow." We know they can go fast. The steam cars are the only ones in which the speed can be regulated to a crawl, but they, too, have their drawbacks and require excessive care, though I think they will prove the "survival of the fittest" in the end. The truth is, the solution of the problem of road motor traffic is a much harder nut to crack than was at first supposed and I fear we shall have to wait some time before we can approach anything like perfection in any system, either oil, steam, or electrical, and the horse will for a yet long time successfully compete with his rivals. Mr. Hirsch is to be congratulated in that he successfully accomplished his journeys. Perhaps it was as much due to good luck as good management, similar to my own experience with the bicycle, only getting one minute tyre puncture in covering nearly 3000 miles of road. I am, Sirs, yours faithfully,

Oct. 8th, 1900. MOTOR-CAR.

To the Editors of THE LANCET.

SIRS,—Medical men who contemplate investing in a motor-car are under an obligation to Mr. Hirsch who gives his experience in THE LANCET of Oct. 6th. I have thought that a steam car would be more suitable for medical work. Will any of your readers who have used these cars kindly give their experience?

I am, Sirs, yours faithfully,

Stockwell-road, S.W., Oct. 8th, 1900 R. J. HEATLY, L.R.C.P. Irel.

"A GHOSTLY JOKE."

THE *Indian Medical Record* is responsible for the following story:—Dr. McTavish of Edinburgh was something of a ventiloquist, and it befell that he wanted a lad to assist in the surgery who must necessarily be of strong nerves. He received several applications, and when telling a lad what the duties were, in order to test his nerves he would say, while pointing to a grinning skeleton standing upright in a corner: "Part of your work will be to feed the skeleton there, and while you are here you may as well have a try to do so." A few lads would consent to a trial and received a basin of hot gruel and a spoon. While they were pouring the hot mass into the skull the doctor would throw his voice so as to make it appear to proceed from the jaws of the bony customer, and gurgle out: "Gr-r-r-gr-h-gh! That's hot!" This was too much, and without exception the lads dropped the basin and bolted. The doctor began to despair of ever getting a suitable helpmate, until a small boy came and was given a basin and a spoon. After the first spoonful the skeleton appeared to say: "Gr-r-r-uh-r-hr! That's hot!" Shovelling in the scalding gruel as fast as ever the boy rapped the skull and impatiently retorted: "Well jist blew on't, ye auld bony!" The doctor sat down on his chair and fairly roared, but when the laugh was over he engaged the lad on the spot.

"THE MOUNTING OF MUSEUM SPECIMENS."

To the Editors of THE LANCET.

SIRS,—F. A. W. (THE LANCET, Oct. 6th, p. 1048) will find useful information in the St. Bartholomew's Hospital Reports, vol. xxxiii., 1897, pp 236-240, *re* mounting museum specimens.

I am, Sirs, yours faithfully,

Cardiff, Oct. 6th, 1900. ELDON PRATT.

A WARNING TO PARENTS.

AT Porth, on Oct. 5th, a woman was charge with having allowed her child to go into the public street while suffering from diphtheria. The proceedings were taken at the instance of Mr. J. Herbert Jones, medical officer of health to the Rhondda Urban District. The evidence showed that the child was notified on August 23rd as suffering from diphtheria and the usual instructions were immediately given to the mother, but on the following day and on subsequent occasions the sanitary inspector found the child out of doors. Since that time four cases of diphtheria had been notified from the street in question. A fine of 30s. and costs was inflicted, making £2 0s. 6*d* in all.

THE MORALITY OF CHEATING.

THE immortal Joseph Surface has many followers, but we think that the following case shows a height of impudence combined with a profession of "duty to one's neighbour" which has rarely been reached. Mr. Charles Theodore Brooks is a dispensing chemist living in Lower Edmonton Of him Mr. A. L. Bridge, an inspector under the Food and Drugs Acts, purchased some mercurial ointment which was found to be deficient in mercury to the extent of 34·67 per cent. It also was made from lanolin instead of lard or suet. Mr. Brooks appeared to explain this little matter on Oct. 4th at the Tottenham Sessions. According to Mr. Bridge the accused had stated in conversation that there was no lard in the ointment because he (Brooks) was a Buddhist and must not handle pig's fat. Mr. Brooks, however, informed the Bench that he merely spoke of lard in an ironical manner. There was lard in his ointment. It was sold for animal purposes and therefore would not be in accordance with the British Pharmacopœia. Mr. Brooks has a proper feeling for his fellow creatures. He explained the slight deficiency in the quantity of mercury by arguing that there would be great danger in selling pure mercurial ointment, for it was a very deadly poison. As a further illustration he would say that a man once asked him for some pure carbolic acid. He supplied him with diluted carbolic acid, which the man drank, and the fact of the dilution saved the man's life. The bench, however, were hard-hearted and fined Mr. Brooks 5s. and 18s. 6*d*. costs. Mercurial ointment, in their opinion, meant the ointment of the British Pharmacopœia. Mr. Brooks sorrowfully said that the bench must take the responsibility. It was a deadly poison.

A NEW WOOD FOR STREET PAVING.

WE have received a specimen block of a wood introduced by Mr. E. Alcott of California, which is being tried in various districts of London for paving the roadways. The wood is called "red gum," and is apparently well adapted for the purpose of making a roadway. It is very dense and fine-grained, in fact the cut cross grain shows an almost velvety surface. It is said not to be absorbent and to have the faculty of binding, so that rain or the washings from horse-dung and urine will have no chance of sinking between the blocks. A section of Piccadilly is at present being laid with this wood and it will be interesting from a sanitary point of view to see how it wears. Probably, however, as soon as it is laid down it will be grubbed up again by the Post Office, the National Telephone Company, an electric lighting company, a water company, a gas company, or a hydraulic power company, and so will not be fairly tested. The sight of a newly-paved roadway is irresistible for such bodies and at present there is no law to stop the annoyance caused by them. We have not heard whether the wood is submitted to any treatment other than ordinary seasoning, but the specimen submitted to us smells strongly of acetic acid, a condition which of course may be accidental.

THE POWERS OF A RURAL SANITARY AUTHORITY.

To the Editors of THE LANCET.

SIRS,—Would you be good enough to inform me in THE LANCET whether a rural sanitary authority has a right to place meters at private houses if they believe that the water has been wasted, and also if they can do it without the consent of the owner of the house?

I am, Sirs, yours faithfully,

Oct. 4th, 1900. WILLIAM MASON, M.O.H.

*** Unless the right to do so [illegible] agreement as a condition of supply we do not [illegible] t exists.—ED. L.

CHANGE-RINGING.

CAMPUS writes:—"Will some reader of THE LANCET who is acquainted with the exercise of change-ringing on church bells kindly give his opinion of the effect of the exercise on health produced by the regular extension of the arms above the head, the position of the body, the mental alertness in observing the moving ropes, counting the place, and remembering the course of the method being rung?"

◆

Practitioner.—Such circulars are highly objectionable but we do not think that the General Medical Council has power to punish their disseminators. There would be no objection, if the practitioner in question is known to spread them broadcast, to writing to the university or corporation to which he belongs and inviting an opinion upon his conduct.

Northumbria.—The essence of the matter rests in the terms of the burial order. A corone [illegible] ect a burial without an inquest, but [illegible] given complaint can be made to hi [illegible] *e* exercise of his discretion would be u [illegible] ve cause to the contrary.

Vincit Veritas should write to the Pharmaceutical Society and the Society of Apothecaries of London.

During the week marked copies of the following newspapers have been received: *Yarmouth Journal, Manchester Courier, Public Health Engineer, Northern Daily Telegraph, Blackburn Standard, Birmingham Daily Gazette, Dundee Courier, Times of India, Pioneer Mail, Nottingham Daily Guardian, Framlingham Weekly News, Lancashire Daily Post, Indian Daily Telegraph (Lucknow), Bradford Observer, Glasgow Herald, Leeds Mercury, Citizen, Architect, Builder, Scotsman, Liverpool Daily Post, Manchester Guardian, Baptist, Bristol Mercury, Sanitary Record, Yorkshire Post, South Eastern Gazette, Oxford Chronicle, West Sussex Gazette, Carpenter and Builder, Mark Lane Express, St. Andrews Citizen, Fife News, Leicester Post, Auckland Chronicle, Jackson's Oxford Journal, City Press, Hastings News, Reading Mercury, Hertfordshire Mercury, Mining Journal, Blackpool Times, Local Government Chronicle, Huddersfield Examiner, Liverpool Journal of Commerce, Surrey Advertiser, Birmingham Daily Mail, Local Government Journal, Stockport Advertiser, Grimsby News, Northampton Herald, Warehouseman and Draper, Cromer Post, Plumber and Decorator, Weekly Free Press and Aberdeen Herald, Devon Weekly Times, Watford Leader, Hereford Times, South Shields Free Press, Derby Standard, Hampshire Independent, Lowestoft Standard, People, Ayr Advertiser, Northampton Daily Chronicle, Worcester Journal* &c., &c.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Let ... tion or for private informa-
the names and addresses of
for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C , are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates, on this or on any other ground, should be resisted The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied, Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

told I may wait till my coffin is ordered, like the man who in the old days waited for improvement in bicycles, but to "dabble" in motor-cars requires a deeper pocket than bicycles and all doctors are not rich. One great element of failure in my opinion is the rage for excessive speed. By a medical man whose work is mixed country and town the first question asked should be not "how fast will it go," but "how slow." We know they can go fast. The steam-cars are the only ones in which the speed can be regulated to a crawl, but they, too, have their drawbacks and require excessive care, though I think they will prove the "survival of the fittest" in the end. The truth is, the solution of the problem of road motor traffic is a much harder nut to crack than was at first supposed and I fear we shall have to wait some time before we can approach anything like perfection in any system, either oil, steam, or electrical, and the horse will for a yet long time successfully compete with his rivals. Mr. Hirsch is to be congratulated in that he successfully accomplished his journeys. Perhaps it was as much due to good luck as good management, similar to my own experience with the bicycle, only getting one minute tyre puncture in covering nearly 3000 miles of road.

I am, Sirs, yours faithfully,

Oct. 8th, 1900. MOTOR-CAR.

To the Editors of THE LANCET.

SIRS,—Medical men who contemplate investing in a motor-car are under an obligation to Mr. Hirsch who gives his experience in THE LANCET of Oct. 6th. I have thought that a steam car would be more suitable for medical work. Will any of your readers who have used these cars kindly give their experience?

I am, Sirs, yours faithfully,

Stockwell-road, S.W., Oct. 8th, 1900. R. J. HEATLY, L.R.C.P. Irel.

"A GHOSTLY JOKE."

THE *Indian Medical Record* is responsible for the following story:—Dr. McTavish of Edinburgh was something of a ventriloquist, and it befell that he wanted a lad to assist in the surgery who must necessarily be of strong nerves. He received several applications, and when telling a lad what the duties were, in order to test his nerves he would say, while pointing to a grinning skeleton standing upright in a corner: "Part of your work will be to feed the skeleton there, and while you are here you may as well have a try to do so." A few lads would consent to a trial and received a basin of hot gruel and a spoon. While they were pouring the hot mass into the skull the doctor would throw his voice so as to make it appear to proceed from the jaws of the bony customer, and gurgle out: "Gr-r-r-gr-h-gh! That's hot!" This was too much, and without exception the lads dropped the basin and bolted. The doctor began to despair of ever getting a suitable helpmate, until a small boy came and was given a basin and a spoon. After the first spoonful the skeleton appeared to say: "Gr-r-r-uh-r-hr! That's hot!" Shovelling in the scalding gruel as fast as ever the boy rapped the skull and impatiently retorted: "Well jist blew on't, ye auld bony!" The doctor sat down on his chair and fairly roared, but when the laugh was over he engaged the lad on the spot.

"THE MOUNTING OF MUSEUM SPECIMENS."

To the Editors of THE LANCET.

SIRS,—F. A. W. (THE LANCET, Oct. 6th, p. 1048) will find useful information in the St. Bartholomew's Hospital Reports, vol. xxxiii., 1897, pp. 236-240, *re* mounting museum specimens.

I am, Sirs, yours faithfully,

Cardiff, Oct. 6th, 1900. ELDON PRATT.

A WARNING TO PARENTS.

AT Porth, on Oct. 5th, a woman was charged with having allowed her child to go into the public street while suffering from diphtheria. The proceedings were taken at the instance of Mr. J. Herbert Jones, medical officer of health to the Rhondda Urban District. The evidence showed that the child was notified on August 23rd as suffering from diphtheria and the usual instructions were immediately given to the mother, but on the following day and on subsequent occasions the sanitary inspector found the child out of doors. Since that time four cases of diphtheria had been notified from the street in question. A fine of 30*s*. and costs was inflicted, making £2. 0*s*. 6*d*. in all.

THE MORALITY OF CHEATING.

THE immortal Joseph Surface has many followers, but we think that the following case shows a height of impudence combined with a profession of "duty to one's neighbour" which has rarely been reached. Mr. Charles Theodore Brooks is a dispensing chemist living in Lower Edmonton. Of him Mr. A. L. Bridge, an inspector under the Food and Drugs Acts, purchased some mercurial ointment which was found to be deficient in mercury to the extent of 34·67 per cent. It also was made from lanolin instead of lard or suet. Mr. Brooks appeared to explain this little matter on Oct. 4th at the Tottenham Sessions. According to Mr. Bridge the accused had stated in conversation that there was no lard in the ointment because he (Brooks) was a Buddhist and must not handle pig's fat. Mr. Brooks, however, informed the Bench that he merely spoke of lard in an ironical manner. There was lard in his ointment. It was sold for animal purposes and therefore would not be in accordance with the British Pharmacopœia. Mr. Brooks has a proper feeling for his fellow creatures. He explained the slight deficiency in the quantity of mercury by arguing that there would be great danger in selling pure mercurial ointment, for it was a very deadly poison. As a further illustration he would say that a man once asked him for some pure carbolic acid. He supplied him with diluted carbolic acid, which the man drank, and the fact of the dilution saved the man's life. The bench, however, were hard-hearted and fined Mr. Brooks 5*s*. and 18*s*. 6*d*. costs. Mercurial ointment, in their opinion, meant the ointment of the British Pharmacopœia. Mr. Brooks sorrowfully said that the bench must take the responsibility. It was a deadly poison.

A NEW WOOD FOR STREET PAVING.

WE have received a specimen block of a wood introduced by Mr. E. Alcott of California, which is being tried in various districts of London for paving the roadways. The wood is called "red gum," and is apparently well adapted for the purpose of making a roadway. It is very dense and fine-grained, in fact the cut cross grain shows an almost velvety surface. It is said not to be absorbent and to have the faculty of binding, so that rain or the washings from horse-dung and urine will have no chance of sinking between the blocks. A section of Piccadilly is at present being laid with this wood and it will be interesting from a sanitary point of view to see how it wears. Probably, however, as soon as it is laid down it will be grubbed up again by the Post Office, the National Telephone Company, an electric lighting company, a water company, a gas company, or a hydraulic power company, and so will not be fairly tested. The sight of a newly-paved roadway is irresistible for such bodies and at present there is no law to stop the annoyance caused by them. We have not heard whether the wood is submitted to any treatment other than ordinary seasoning, but the specimen submitted to us smells strongly of acetic acid, a condition which of course may be accidental.

THE POWERS OF A RURAL SANITARY AUTHORITY.

To the Editors of THE LANCET.

SIRS,—Would you be good enough to inform me in THE LANCET whether a rural sanitary authority has a right to place meters at private houses if they believe that the water has been wasted, and also if they can do it without the consent of the owner of the house?

I am, Sirs, yours faithfully,

Oct. 4th, 1900. WILLIAM MASON, M.O.H.

*** Unless the right to do so has been acquired by agreement as a condition of supply we do not believe that such right exists.—ED. L.

CHANGE-RINGING.

CAMPUS writes:—"Will some reader of THE LANCET who is acquainted with the exercise of change-ringing on church bells kindly give his opinion of the effect of the exercise on health produced by the regular extension of the arms above the head, the position of the body, the mental alertness in observing the moving ropes, counting the place, and remembering the course of the method being rung?"

Practitioner.—Such circulars are highly objectionable but we do not think that the General Medical Council has power to punish their disseminators. There would be no objection, if the practitioner in question is known to spread them broadcast, to writing to the university or corporation to which he belongs and inviting an opinion upon his conduct.

Northumbria.—The essence of the matter rests in the terms of the burial order. A coroner has an undoubted right to direct a burial without an inquest, but if such direction be improperly given complaint can be made to his superiors, by whom the *bonâ fide* exercise of his discretion would be upheld unless there were very grave cause to the contrary.

Vincit Veritas should write to the Pharmaceutical Society and the Society of Apothecaries of London.

During the week marked copies of the following newspapers have been received: *Yarmouth Journal, Manchester Courier, Public Health Engineer, Northern Daily Telegraph, Blackburn Standard, Birmingham Daily Gazette, Dundee Courier, Times of India, Pioneer Mail, Nottingham Daily Guardian, Framlingham Weekly News, Lancashire Daily Post, Indian Daily Telegraph (Lucknow), Bradford Observer, Glasgow Herald, Leeds Mercury, Citizen, Architect, Builder, Scotsman, Liverpool Daily Post, Manchester Guardian, Baptist, Bristol Mercury, Sanitary Record, Yorkshire Post, South Eastern Gazette, Oxford Chronicle, West Sussex Gazette, Carpenter and Builder, Mark Lane Express, St. Andrews Citizen, Fife News, Leicester Post, Auckland Chronicle, Jackson's Oxford Journal, City Press, Hastings News, Reading Mercury, Hertfordshire Mercury, Mining Journal, Blackpool Times, Local Government Chronicle, Huddersfield Examiner, Liverpool Journal of Commerce, Surrey Advertiser, Birmingham Daily Mail, Local Government Journal, Stockport Advertiser, Grimsby News, Northampton Herald, Warehouseman and Draper, Cromer Post, Plumber and Decorator, Weekly Free Press and Aberdeen Herald, Devon Weekly Times, Watford Leader, Hereford Times, South Shields Free Press, Derby Standard, Hampshire Independent, Lowestoft Standard, People, Ayr Advertiser, Northampton Daily Chronicle, Worcester Journal &c., &c.*

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

An Address

ON

JOHN LOCKE AS A PHYSICIAN.

Delivered before the Students' Societies of the Medical Department of the University of Pennsylvania, on Jan 16th, 1900,

BY WILLIAM OSLER, M.D., F.R.S.,
PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY, BALTIMORE.

GENTLEMEN,—Among the great men of the seventeenth century not one has more enduring claims to our grateful remembrance than John Locke—philosopher, philanthropist, and physician. As a philosopher his praise is in the colleges. As the apostle of common sense he may be ranked with Socrates and a few others who have brought philosophy from the clouds to the working-day world. Of his special virtues and qualifications as the typical English philosopher nothing need be said, but were there time I would fain dwell upon his character as a philanthropist—in the truest sense of the word. The author of the Epistle on Toleration, the Treatise on Education, and the Constitution of Carolina, the man who pleaded for "absolute Liberty, just and true Liberty, equal and impartial Liberty," the man who wrote the memorable words, "All men are naturally in a state of freedom, also of equality," must be ranked as one of the great benefactors of the race.

With the faculty Locke's connexion has usually been described as "loose and uncertain." Indeed, we know him chiefly as a friend of Sydenham. Until the appearance of Fox-Bourne's "Life" it had not been recognised that he was at times an active practitioner, and that throughout the greater part of his long life he was ready to treat cases and to give advice; still less was it known that he was a writer of medical essays, and that he had left a large body of clinical reports and papers. I had become familiar with his professional relations through John Brown's essay, "Locke and Sydenham," and many additional details are given in the "Life" just referred to, but for the more important facts I have made a careful study of the Locke MSS in the British Museum and in the Record Office.

I.—LIFE

Let me first give a brief summary of Locke's life. He was born in the county of Somerset in 1632, the son of an attorney who at the outbreak of the civil war joined the Parliamentary side. Of his boyhood and early education but little are known In 1646 he entered Westminster School under the famous Dr. Busby, where he had as fellow students Richard Lower, Walter Needham, [illegible] Mapletoft, who subsequently [illegible] In 1652 he entered Christ Ch[illegible] B.A. degree in 1655 and the [illegible] year he became senior student [illegible] 1660 lecturer on Greek, and in 1662 lecturer on Rhetoric. In 1665 he served as secretary to the embassy of Sir Walter Vane to the Elector of Brandenburg. Until 1660 a student of classics and rhetoric, Locke appears to have been at a loss to know exactly what calling to follow. Thoroughly disgusted, he had broken with the old scholastic philosophy and, imbued with the new leaning of Bacon and Descartes, felt what Donne calls "the sacred hunger of science." But what probably turned his attention most actively to medicine was the presence in Oxford of the celebrated Robert Boyle, who with his associates had formed a scientific club, the "invisible college," which became the nucleus of the Royal Society Letters of this period show Locke to have been busy with experimental physics, working at problems suggested by Boyle, taking daily notes on the weather (a practice which he kept up for many years), and gradually becoming well versed in the sciences cognate to medicine Unfortunately we have very little information as to the character of his medical studies, which seem, however, to have been of a rather desultory nature, as he did not comply with the very easy requirements for the degree. On these Fox-Bourne makes the following comment: "All that was expected from [illegible] ship in physic w[illegible] the lectures of [illegible] of anatomy and [illegible] certain number [illegible] after that little more than a delay of four years was necessary to qualify him fo[illegible] lectures, delivered every [illegible] during term, were limited t[illegible] of Hippocrates and Galen [illegible] in the spring to attend the [illegible] and to hear four lectures, each two hours long, upon it, and in the autumn to hear three lectures [illegible] These requirem[illegible] in November, [illegible] that he could [illegible] becoming a ba[illegible] ever, was not [illegible] belonged to the Puritan party. During these years he seems to have been intimately associated with Dr. David Thomas, at that time a practitioner at Oxford. He writes to Boyle in February, 1666 67. "Mr. Thomas presents his humble service to you He and I are now upon a new sort of chemistry; that is, extracting money out of the scholars' pockets, and if we can do that, you need not fear but that in time we shall have the lapis, for he that can get gold and silver out of scholars cannot doubt to extract it anywhere else." Tho[illegible] unavailing to procure the docto[illegible]ing with the regulations, it was [illegible] in his senior studentship at Ch[illegible]ally held only by persons in holy orders, and this post, with the salary attached to it, Locke enjoyed till his expulsion in 1684.

Locke did not receive the bachelorship of medicine until 1674, in which year he was appointed to one of the two medical studentships at Christ Church, and it was supposed by his friends that this was a step preliminary to taking the doctor's degree, but to this he never proceeded. In 1666, when acting as an assistant to Dr. Thomas, Lord Ashley, afterwards the first Earl of Shaftesbury, the celebrated Achitophel of Dryden's satire, came to Oxford to drink the waters of the Astrop wells. He was the subject of a remarkable malady of which I shall subsequently give a detailed account. Dr Thomas, to whom he had written to have the waters ready for him, was away but had left word with Locke to get them, and as there was some trouble and delay Locke called on Lord Ashley to apologise. [illegible] a mutual attractio[illegible] friendship between [illegible] as in the following [illegible] House, the London residence of Lord Ashley, as physician and literary factotum.

From this date until 1675 Locke lived in Lord Ashley's family, occupying himself in all sorts of miscellaneous duties, some domestic, as finding young Anthony Ashley a wife, whom he subsequently attended on several interesting occasions. One duty which interests us in America very much is the share which he took in the Carolina colony. As secretary to the Lords Proprietors he was appointed one of the Landgraves and wrote, it is supposed, the celebrated "Fundamental Constitutions of the Government of Carolina," the original draft of which (in his handwriting), with many alterations and erasures, may be seen in the Record Office. The celebrated clause, "No person whatsoever shall disturb, molest, or persecute another for his speculative opinions in religion or his way of worship," expresses the spirit of toleration for which Locke strove all through his life. Subsequently, after Lord Ashley was raised to the peerage as the Earl of Shaftesbury, Locke became Secretary of Presentations During all this period he was deeply interested in medicine and was in intimate association with Sydenham, with Mapletoft, and with other well-known physicians of the day, though it was not until 1674 that he took his M.B. at Oxford About this time he began to suffer much in his health and in 1675 he went to France, where he remained, chiefly at Montpellier and Paris, for four years His journals during this period, which are very full, indicate his continued interest in the profession, though, as he writes to Mapletoft, "My health, which you are so kind to in your wishes, is the only mistress I have a long time courted, and is so coy a one that it will take up the remainder of my days to obtain her good graces and keep her in good humor. She hath of late been very wayward, but I hope is coming about again." In another letter he was a painless internal tumour, broad, and slightly projecting, about the anterior region of the liver, and his hypochondria was very apparent to the touch. Although it had been observed 12 years before, the exact time when the tumour first began is uncertain. For since the colour of the skin was unchanged and no swelling was apparent externally, unless the hand were applied it easily escaped the eye; nor through the whole 12 years did it seem to change in the least. The doctors called into consultation on this point, amongst whom were some from the excellent London college, were inclined to the opinion that this firm and unchanging extuberance was not a morbid tumour, but rather some congenital and unusual malformation of the liver. However the patient himself suspects, not without reason, that the tumour first came into existence in the year 1656, especially as at that time ...... he used to fatigue himself overmuch. By too frequent over-exercise his blood became so heated that his skin would immediately be suffused with a deep redness, and his whole body seemed to be inflamed, all which gave rise to a burning fever. From this time on he was conscious of a complete change in the general condition of his body. Whereas before he was troubled more frequently with pains in the left side, and other splenic symptoms, from now on he escaped absolutely free from these troubles, and in their place acquired a constitution prone to other disorders, and especially susceptible to morbus regius.[2] From the prolonged languor brought on by this disease, when his emaciated body and impaired strength would threaten death, he was frequently restored by the timely use of acidulæ, by means of which he obtained relief for one or two years, and was carried through so many vicissitudes of health, scarcely escaping with his life, until last summer. Then, happily, an internal abscess at last broke out, bringing to a head the source of so many disorders. There is one thing here which I cannot pass by, and that is that the patient's head never once ached though more than fatigued by disease. This, however, is not the only marvel displayed by that head.

"During a bad night about the end of May, 1668, he was suddenly seized with excessive vomiting, accompanied by much disturbance. Everything he had eaten in the preceding meal was rejected, still raw and undigested, in repeated vomitings. He was purged next day by Dr. Glisson, the learned physician-in-ordinary. On the following morning he appeared discoloured a rusty red, which the physician tried to remedy with suitable drugs. But although the face seemed to return a little to its proper appearance, so that he could go about the ordinary duties of life, nevertheless, the languor and loss of appetite returned, anti-icterics and chalybeates being administered in vain. Moreover, about the beginning of June, since all the symptoms were running from bad to worse, the physician prescribed a purging pill to be taken at bedtime. When the patient raised himself up in bed to pass his urine about midnight he was suddenly seized about the region of the stomach and liver with a most acute pain which lasted the greater part of an hour and was finally relieved by resting comfortably in bed. When after an hour or two he again sat up in bed the same excruciating pain returned. Again one hour afterwards he got up, and in the same way when he raised himself upon his buttocks the pain attacked him for the third time, and after a like interval left him. Next morning at 8 o'clock, shortly after taking a purging potion he vomited it up mixed with viscid phlegm. After a while he left his bed, his servants taking him in their arms and placing him upright on his feet, so that his body should nowhere be bent. The cathartic had a satisfactory effect and he was purged. However, though he turned his body, he did not dare bend it, lest the severe pain should come on again. In the evening he began to suffer most acute pain in the back about the loins. This ceased after a quarter of an hour, and at the same there suddenly sprung up below the ensiform cartilage a soft tumour the size of an ostrich egg. It was yielding to the touch, but on being compressed it did not for a moment retain any traces of the fingers. The skin was a *brown* (?) *colour*. There was hardly any pain, and no inflammation. This tumour could not be broken up by the drugs which were administered for six or seven days. Then physicians and surgeons were called into consultation and on June 12th it was opened by the application of cautery. This fact is worthy of observation: before the opening of the tumour a somewhat tenacious and flexible plaster fastened itself so firmly to the skin at the border of the tumour that it could not be torn away without leaving behind a large part of its substance; while, on the other hand, the top of the tumour, about the width of an English half-crown or more, was not even discoloured by it, nor was the plaster at all adherent in that part." The daily record of the case is in English.

"The 12th of June, 1668, in ye morning a caustick was applied and ye same opened in ye afternoon, at wh. dressing besides a large quantity of purulent matter, many bags and skins came away. The like hapned the next day (being Saturday) both in ye fore and afternoon. On Sunday morning (being ye 14th) at ye first drawing out ye tent, a great quantity of yellow choler gushed out and two or three sluffs, wth some tollerable matter at ye latter end, for ye evening only a little matter came forth. And ye like on Monday both morning and evening.

On Tuesday morning a great quantity of matter came forth, with many bags to ye number of at least 80, for ye afternoon little or nothing, and so also on Wednesday.

On Thursday morning we had a new flux, both of matter and skin, in ye afternoon nothing considerable.

A Friday a wax candle was put deep into ye abscesse, and after ye drawing it out some matter and divers sluffs proceeded, in ye afternoon nothing.

20. On Saturday morning and eveninge some matter followed and above 10 bags. The passage could not be found.

21. On Sunday a wax candle put in of four and three-quarter inches and there left until evening, then drawn out without matter.

22. Monday morning. No running: a sponge tent put in for ye afternoon ℥iii matter, bags above 20.

23. Tuesday morning. No running, ℥i of injection for ye evening--℥iii *or iiii injection*, part whereof wh. some matter came away and about 10 bags. About two hours after more came and so ye next morning, at my Lds. rising and about 10 bags at both times.

24 At ye dressing in ye morning, nothing came. Of injections ℥v. or vi., about three in ye afternoon a great flush brought away about 50 sluffs, whereof most were bags (but not red as formerly by reason of the injection) and some like jelly. At ye evening dressing no running. A glove thick spung tent left in ye orifice.

25. Morning. It ran of itselfe a little before dressing. Injection being made there came forth much thin digested looking matter, somewhat fœtid with about 12 bags, whereof one very large. A spung tent put in. In ye evening injection, which came away next morning before dressing wth four or five sluffs.

26. A Friday morning, injection was made & some thin matter came forth. A short spung tent put in: in ye afternoon some matter, but no sluffs.

27. Upon ye drawing out ye spung tent matter followed wth six or seven sluffs. Of injection being made whereof much stayed behind, in ye afternoon ye spung tent being pulled out, a great flush of matter followed, wth almost 20 sluffs. Of injection was made whereof a great part staid in. A hemp tent was put in. Some matter came out in ye night & left a yellow tincture on ye cloths.

28. Pulling out ye tent, some yellow matter came out wth three or four skins. A spung tent put in. The like issued in ye afternoon. Of injection was made & a flax tent put in.

29. It ran in ye night. Next morning after injection a flush of yellowish matter issued wth 18 sluffs. A spung tent put in, after injection, whereof a considerable part remained. In ye afternoon upon ye drawing out ye spung tent, much matter gushed forth, being somewhat fetid, with 12 or 14 sluffs and bags. On injection being made ye same came freely forth, tinctured with matter. A flax tent was put in.

30. In ye morning little matter came out, yellow tinctured, wth one or two skins. A spung tent was put in. For ye afternoon a little matter, wth two or three small sluffs. A flax tent put in.

July 1st. A Wednesday morning. After a second injection much yellow matter came forth wth three or four yellow sluffs, & at last a considerable quantity of whitish well digested matter came out. A flax tent put in. At ye pulling out whereof in ye afternoon some thin matter proceeded & after injection more but little discolored & only two sluffs. A flax tent put in. My Ld. complained of a little paine, lower towards his right side.

2. Upon ye opening on Thursday morning, some little

---

[2] Jaundice.

matter came [illegible] wth one small [illegible] A spung tent put in, In ye evening little came forth, no bags. A spung tent put in wth one injection.

3. The spun[illegible] nshed out, without [illegible] after-ward five or [illegible] [illegible]quor. Injection was made and spung tent put in.

4. Saturday morning. Upon pulling out ye tent little proceeded. After ye putting in ye small catheter & injection made considerable quantity of matter issued. A spung tent was put in; for ye afternoon a large quantity of well digested matter came out. No injection made. A spung tent put in.

5. Yellow matter came forth with four or five sluffs, [illegible] siphon. After [illegible] fternoon being [illegible] well digested, [illegible] iphon. A few [illegible] put in. [illegible] phon were put forth, whereof three or four large ones. A hollow tent was put in upon ye pulling out whereof a sluff came forth, wth divers very little ones; more seemed to stop ye passage but could not issue, because ye thinner parts did run out before through ye hollow pipe. Neither did *injection* promote their coming forth, though some matter of a brownish colour came out.

7. Much yellow matter ran in ye night and some more this morning, with two or three sluffs Injection was made, whereof ye greatest part came forth. A spung tent was put in. At night a sluff stuck to ye tent at its pulling out & 4 or 5 more where 2 very yellow came afterwards No injection. A silver hollow tent put in.

8. It run very much in ye night, ye napkin was stained with yellow and green, one bag. A spung tent put in. In ye evening 4 or 5 sluffs, some matter. An open pipe put in.

9. Little run all night and sluff stopt ye pipe One or two more followed, a considerable quantity of atheromatous matter. At night two sluffs; very little atheromatous matter.

10[3] A great running through ye hollow pipe, two or three sluffs. The matter at last being whiter and more even than before. Much running till night. Some sluffs. Injection made and a hollow pipe put in, after most of ye injection was discharged After this a pain supervened in my Ld's back about ye region of his liver, & at night he vomited; and had a cold shivering; wh. seemed to proceed from somewhat too liberal diet that day & catching some cold

11.[3] After a little sweat in ye morning, my Ld. was better. He was not drest till ye afternoon: ye ulcer having very much discharged itselfe in ye meantime; wth some few sluffs.

12.[3] A little matter wth few sluffs. Injection made. A hollow pipe. At night run very little. Two sluffs.

13 Not drest in ye morning. Ran much. At night little matter, 2 or 3 sluffs.

14 It ran much yellowish gleet and matter in ye night. But upon ye opening no matter nor sluffs issued, though injection were made. At night one yellow sluff & a little good whitish matter.

15. In ye night it ran much yellow matter & about six small sluffs. Injection made. No meeting in ye afternoon.

16. Upon opening much running of yellow matter appeared, with 4 or 5 yellow sluffs.

17. A large flux of yellow liquid, wth 4 or 5 yellow sluffs, whereof two large ones sticking in ye pipe. Injection made

18 It had run somewhat copiously before dressing, wth ye ejection of one very small yellow bag. Injection being made brought forth some matter & a considerable quantity of very yellow liquor.

19. Little running before dressing, after it none, no injection.

20 Small quantity (?) of lesse yellow liquor run before dressing, 4 or 3 sluffs. Injection made.

21 Yellow liquor has continued running. No sluffs nor injection

22 Some pretty laudable yellowish matter came out upon dressing. Injection was made

23 A little matter issued upon coughing. No injection.

24 The like today

No injection.

From the long-standing character of the tumour and the character of the material which escaped—the innumerable bags—there can be no doubt that the disease was hydatids of the liver, [illegible] had, as is so often [illegible] e first instances on [illegible] The use of the sympathetic powder on the 10th, 11th, and 12th shows how strongly popular feeling had affected the profession.

Naturally, from the prominent position of the patient and the strange character of the disease, the case attracted unusual attention. The point that concerned Lord Shaftesbury himself most acutely was whether it was better to remove the silver drainage-tube or to keep it in. To get the opinion of the faculty on the subject, he sent, with Locke's assistance, a circular letter containing the following questions:—

"1. Which is most advisable, to resolve to keep it constantly open, or to heal it up as soon as conveniently may be?

2. Whether, if it be healed up at all, one of these two dangers is not like to follow; either a new collection of matter, the imposthume lying below ye orifice by which it vents itself, or a feaver upon stopping of so considerable an issue?

3. Whether if it be to be healed up at all it be not necessary to keep it open as long as any flux of matter comes through the pipe more than would be from an issue of the Depth and Bigness of ye pipe?

4. Whether the pipe that is now in be not of the fittest length and bigness to be worne constantly to keep it open.

5. Whether whilst it is best open it be not best to dresse it but once in two days, especially in cold weather?

6 Whether whilst it is best open it be convenient to use any Injection, how often & of what sort & to what purpose?

7 Whether if it be kept long open it will be in danger of growing in a worse condition than a simple issue of that depth, either by turning to a foule ulcer or a fistula or any other way, and if there be any such danger how to be prevented?

8 Whether the bare keeping in a Silver pipe will, without paine, keep it open as long as one pleases?

9 Whether I may travel in a coach, ride on horseback, boate, or use any such exercise safely with a pipe in of this length?

10 Whether if it be kept long open Nature will not in time so fortify the parts about the end of the Pipe as to make the danger it may bring by rubbing upon them in any exercise, very little or none at all?

11 Whether during the time it is kept open frequent purgeing be necessary and how often?

12. Whether if it should be kept always open it is not to be feared that a constant flux of matter from it, especially if it should continue to be of any considerable quantity, may very much weaken and emaciate the body, & how to be prevented." (Handwriting not Locke's)

To this circular there are among the Shaftesbury papers the replies of Locke, of Sydenham, of Glisson, of Sir George Ent, of Micklethwaite, of Timothy Clark, and of the Abbé Beaupreau of Angers, an eminent French physician. With the exception of Clark, who urged that the issue should be healed, the *opinions agree* in the main. They are too long to quote at length, but those of Locke and Sydenham are of sufficient historical interest to be given.

"*Consilium Abscessus* (*Locke*).

1 It is better to heal it up as soon as it may safely be done. [illegible] constant issue of that [illegible] collection of matter I think it will be

3 Convenient not only till the flux of matter be no more than may be well expected from a flesh issue of that depth, but after it hath gradually decreased to that small thing, it be kept open at least three or four months at what time soever the flux come to that low ebb, but if it happen after Xmas, as in the spring, that it be kept open till the beginning of the next winter, that the flux be constantly and warily observed, and that it be sometimes diligently searched, so that by these ways all the security possible may be had that there is not the least sore or hollow left

---

[3] The sympathetic powder made use of.

preface is a sharp and stout defence of the new method, in which it must be confessed Locke does not spare the colleagues of his friend. "How much some of my own faculty have fomented and increased these reports, they themselves know, and with what design I leave it to their own consciences to tell them, only they must give me leave to say it would have become them out of common charity as good men, as well as out of an obligation to improve their art and save men's lives as physicians, upon the first intimation of an unusual method of curing so common a disease as this is, to have inquired more particularly of the way, observed the circumstances, and informed themselves of the events before they cried it down as dangerous and fatal, and frighted all that came within their reach from an enquiry into or trial of his method by the abhorrency they had given them against so bold and hazardous a practice." Evidently Sydenham smarted under the calumnies and misrepresentations and the preface speaks of "the greatest indignities beyond almost the sufferance of a man, and the endangering not only of my reputation and livelihood, but even my life itself." The article is chiefly valuable from the account which it gives of the steps by which Sydenham was led to adopt his cooling treatment. Neither dedication nor preface was ever used. The projected work did not appear and many years later the "Observationes Medicæ," which contained his matured experiences, was dedicated to Mapletoft and another preface was used.

V.—JOURNALS, LETTERS, AND COMMONPLACE BOOKS

A keen observer, a constant note-taker, and of most neat and accurate literary habits, Locke has left a large mass of manuscript, which has been carefully searched and sifted by Mr. Fox-Bourne, in whose Life, as well as in that by Lord King, there are many letters and extracts illustrating his work as a physician. The letters to Mapletoft about Lady Northumberland have been referred to. Of the journals those of his Holland sojourn, which are said by Fox-Bourne to contain much of medical interest, I have not yet seen. In the British Museum is a very characteristic journal in which one may follow Locke's medical work for the year 1679. It is bound with an *Ephemeris* or Calendar of the year. He was in Paris during the early months. As usual he was interested in bills of mortality and he states (Jan. 16th) that the deaths in Paris were from 19,000 to 20,000 a year. He makes a note to ask if the deaths of Quakers, Anabaptists, and Jews are recorded in London. On April 12th he comments on the handbills set up about town with a receipt to kill lice. There are many notes on the treatment of diseases and receipts, to the collection of which he seemed very partial. He queries whether the sympathetic powder could be of any use in dentium dolor, indicating that he still had a lingering belief in it. There are many notes on various topics and memoranda about books, &c. On May 8th he sailed from Calais. On June 4th are brief notes of a Mr. N., sick of a fever, whom he bled, and afterwards jaundice appeared. Notes on vomiting, diseases of the eye, icterus, hernia, hysteria, hypochondria, rheumatism, mania, and tussis occur in June. On August 18th he was sent for in consultation in the case of Mr. Beavis of Olanligh, Kent, and for the next six weeks the Journal is very full, containing a detailed account of the symptoms of Mr. Beavis and the treatment, many notes on the practice of Dr. Jacob, the attending physician, and a characteristic description of two attacks of fever with which he was himself attacked. Mr. Beavis had a long illness, possibly typhoid fever, and it was not until the end of September that Locke left for London.

The Bodleian Common-place Book with the Anecdota Sydenhami.—This is a small folio, bound in parchment, which originally contained 400 pages, of which 247 are torn out. Dr. W. G. Greenhill published a part of the manuscript in 1845 as "Anecdota Sydenhami," and the following extract from the preface may be quoted: "They are taken from a MS. in the Bodleian Library at Oxford (Rawl. C. 406), very neatly (and for the most part very legibly) written, apparently about the end of the seventeenth century. The name of the writer is not mentioned nor is anything known of the history of the MS., except that it once belonged to Dr. Richard Rawlinson and forms part of the collection of MSS. bequeathed by him to the University of Oxford about the middle of the last century. At the beginning of the volume (of which about two-thirds have been torn away) are these words: 'Extracts of Sydenham's Physick Books and some good Letters on Various Subjects.' This is the whole of the *external* evidence respecting the genuineness of the following Anecdota; and perhaps, if there were nothing more to say in their favour, it might be doubted how far the editor was justified in giving them to the world under the sanction of the name of Sydenham: the *internal* evidence, however, is much more conclusive, and indeed to his own mind perfectly satisfactory. The writer professes to have been acquainted with Sydenham himself, and to have originally written the following Notes, partly from his dictation in the years 1682, 1683, and partly from some of his MSS. written chiefly in 1670. These Notes he appears to have revised and written out correctly in their present form *after* 1685 (as he refers to the edition of Sydenham's Work published in that year), and (if the editor's conjecture at p. 69 be correct) *before* 1692, as that is the date of the first edition of the *Processus Integri.*"

Apparently it was not until Mr. Fox-Bourne examined the manuscripts that it was recognised as belonging to Locke, whose handwriting is most distinctive. While largely made up of extracts from Dr. Sydenham's physic books, the *excerpta ex ore Sydenhami* dated 1682–83; show the maintenance at this date of an intimate professional relationship between the two great men.

The other medical papers in the volume illustrate the wide scope of Locke's inquiries. There are statements about the Peruvian bark and the best methods of its preparation. But the chief interest after the Sydenham notes relates to a sort of collective investigation which Locke instituted on public health. He seems to have had a deep conviction that much good would follow a careful study of the bills of mortality. His circular letter contains the following inquiries (MS., p. 68): "1. What bills of mortality are kept in foreign countries, either as to the diseases of which persons die, or the number who die weekly or yearly in the most capital cities or towns of Europe or other parts of the world, as Paris, Madrid, Amsterdam, Venice, Hamburg, Rome, Constantinople, Smyrna, Dublin, Edinburgh, &c., as also in New England, Barbadoes, Jamaica, and other Plantations. 2. The aire of different countries, with the temper and alteration of the same at the different seasons of the year, and the diseases those countries are subject to and the time when. 3. The opinion physicians have of Jesuit's bark, and the best account they can give of it. 4. The esteem which physicians have had of Dr. Sydenham and his works. 5. The order observed in foreign countries as to physicians, surgeons, apothecaries and herbalists for the improvement of travellers and young students."

There are answers from several correspondents. Dr. Willoughby of Dublin (April 17th, 1691) gives a tabular account of the bills of mortality between 1682–90 (inclusive), and a description of the air of the country. He speaks of the Peruvian bark as "the only specific I know in nature." Of Dr. Sydenham he says, "he has been very honest in rescinding from Physick all the unnecessary pomp of alteratives and preparatives and reducing it to the use of the grand remedies which in Physick do justly fill both sides of the loafe." In another place is an account of Dr. Willoughby's proposal for the improvement of agriculture in Ireland, the important part of which was that every proprietor who will not improve his waste land shall make over four-fifths of it to the Crown. There is a brief statement of the Amsterdam bills of 1691 and 1693, and an account of Dr. Bett's proposal to the Lord Mayor for the improvement of the returns in London. There are letters from James Young of Plymouth about various diseases, and one from Dr. Eales (?) giving an account of Dr. Morton's books, in which "he has improved the hints of our good friend the great Dr. Sydenham admirably well." Dr. Patrick Dun sends a full statement about the mortality bills of Dublin, and pp. 93 to 96 of the MS. contain *in extenso* the death-rates from Jan. 1695 to April, 1698. Pages 110 to 357 are torn out, but from the index, pp. 369–371, we can glean the contents of the missing leaves—books whose authors are unknown, "books to be wrote," and "books wrote in defence of the murder of King Charles I," with a long list of the authors, and about the "*Eikon Basilike*" and the various controversies upon it, extending from pp. 199 to 236.

Though qualified and deeply interested in both the science and the art of medicine Locke never became, as Fox-Bourne says, "in any orderly way a physician." Until he left England in 1683 "he was still waiting for an opportunity of devoting himself steadily to his favourite occupation. He was still generally spoken of by his friends as Dr. Locke, and he still regarded himself as before everything else a doctor." Hereafter questions of philosophy, finance, education, trade, theology, &c., occupied his busy life, but through it all, and to the very end, there are references in his letters and journals to show that his first love was not forgotten. In the memorable and oft-quoted letter to Dr. Thomas Molyneaux in praise of Sydenham's method, Jan. 20th, 1692-93, he speaks of himself as one who wishes well to the practice of physic "though he meddles not with it," yet in the same year we find him prescribing for a friend's wife. In 1694 he is corresponding with Dr. Hans Sloane on medical matters. In January, 1697-98, King William consulted him, believing that they suffered with similar diseases. In 1701 he writes again to Sloane about a patient with an obstinate fever, and in the following year he gives very wise advise to his old friend Lomborch, who was ill. Evidently Locke's clear, strong judgment was valued by his friends in all relations of life, and as Somers and other politicians turned to him for instruction in questions of trade and finance so his friends and others insisted upon utilising his medical knowledge. Sydenham, Boyle, Thomas, Mapletoft, and Molyneaux had been his intimate associates. In Montpellier, in Paris, and in Holland he had been a welcome guest in medical circles, and in London we have met him in consultation with the most eminent practitioners of the day upon a most important case and handing in a written opinion as their colleague and equal.

For each one of us there is still a "touch divine" in the life and writings of John Locke. A singularly attractive personality, with a sweet reasonableness of temper and a charming freedom from flaws and defects of character, he is an author whom, liking at the first acquaintance, we soon love as a friend. Perhaps the greatest, certainly, as Professor Fowler says, the most characteristic, English philosopher, we may claim Dr. Locke as a bright ornament of our profession, not so much for what he did in it, as for the methods which he inculcated and the influence which he exercised upon the English Hippocrates. He has a higher claim as a really great benefactor of humanity, one of the few who, as was so finely said of Isocrates, "reflected the human spirit always on the nobler side." One of Locke's earliest writings was a translation for Lady Shaftesbury of Pierre Nicole's Essays, in one of which, on the "Way of Preserving Peace with Men," Locke seems to have found a rule of life which I commend to you: "Live the best life you can, but live it so as not to give needless offence to others; do all you can to avoid the vices, follies, and weaknesses of your neighbours, but take no needless offence at their divergences from your ideal" (Fox-Bourne)

The Hunterian Lecture

ON

THE CLINICAL STUDY OF HEART DISEASE.

Delivered before the Hunterian Society on Oct. 10th, 1900,

BY NORMAN MOORE, M.D. CANTAB,
F.R.C.P. LOND,
ASSISTANT PHYSICIAN TO, AND LECTURER ON MEDICINE AT, ST. BARTHOLOMEW'S HOSPITAL.

GENTLEMEN,—The great man whom your society commemorates had made many observations on the vascular system in men and in animals, some of which are preserved in his interesting "Treatise on the Blood, Inflammation, and Gunshot Wounds," written in 1793. He describes a patient who from boyhood had suffered from shortness of breath, palpitation, attacks of venous engorgement, and irregular action of the heart, and who died from dropsy. Post mortem John Hunter found the aortic valves to be thick, hard, and contracted, and he remarks: "This diseased structure of the valves accounts for every one of what may be called his original symptoms, and was such as to render them [i.e., the valves] of very little use; the blood therefore must have fallen back into the cavity of the ventricle again at every systole of the artery." He discusses whether this state of the valves was a natural formation or a disease, and points out the wide effect on the circulation of such a condition. "It may be difficult," says Hunter, "to account for the increased size of the heart, whether it was a mechanical effect, as the blood would be thrown back into it at every systole of the aorta and diastole of the heart, or whether it arose from a particular affection of that viscus. The first idea is the more natural, but it is not necessary that the cause should be of this kind, for we see every day enlarged hearts where the symptoms have been somewhat similar, and yet no visible mechanical cause existed, and indeed it is a common effect where there is an impeded circulation." The account shows us how far a case of heart disease was understood by Hunter, and his views may be taken as the most advanced of his time. He had perceived how valvular disease led to palpitation, shortness of breath, venous engorgement, and dropsy, and he suspected, but was not sure of, the causal relation of aortic valvular disease to hypertrophy of the left ventricle. He was clearly not familiar with affection of the aortic valves as a very common disease; he does not seem to have considered whether the mitral orifice admitted regurgitation, as it very likely did in such a case and in some of the other examples of hypertrophy which he mentions; he knew nothing of the association of renal disease with hypertrophy of the left ventricle; and of course he was unacquainted with the method of ascertaining valvular disease by auscultation of the heart.

Hunter gave all the time at his command to the original observation of nature and did not pay much attention to the books of the past or of his own time. He had probably never read the account of an enlarged heart in which extensive disease of the aortic valves was found post-mortem which Dr James Douglas had given in the "*Philosophical* Transactions" for 1716. Douglas had heard during the patient's life a loud sound proceeding from the cardiac area, the systolic murmur of aortic stenosis with which we are all perfectly familiar. Had Hunter read this observation and considered it in relation to his own observation on disease of the aortic valves it does not seem improbable that he might have anticipated part of Laennec's subsequent discovery and have initiated the auscultation of the heart and elucidated the meaning of valvular murmurs. Douglas has not, I think, received sufficient honour for his remarkable observation. He was a man of great ability, great industry, acute observation, and extensive learning. He died in 1742 and left behind him numerous medical, pathological, and anatomical observations[1] of a high order, some botanical works of interest[2] and an admirable bibliography and summary of all anatomical writers from Hippocrates to Harvey.[3] He merits the honourable commemoration which he receives whenever the fold of Douglas is mentioned. The human body, a nobler structure than any temple made with hands, is a kind of Westminster Abbey for the first centuries of anatomists. There Willis, Fallopius, Malpighi, Tulpius, Lower, Wharton, and Glisson all have their monuments, more suitable to their work and more to their own taste than any "storied urn or animated bust." Douglas well deserves his place in that *temple of fame*. With regard to diseases of the heart we feel that we know a great deal more than he did, much more even than John Hunter did. Vast have been the additions to knowledge in that subject since Hunter's century. Dr. Mead was the most famous physician of London in Hunter's childhood, and in his medical writings all he has to say about heart disease fills only two small pages. We have at our disposal works on heart disease the titles alone of which fill 92 large pages with double columns of the catalogue of the Surgeon General's Library at Washington, that admirable aid to study which we owe to the organising skill and indefatigable industry of Dr. Billings. Notwithstanding this vast accumulation of knowledge in the hands of the medical profession of to-day, difficulties still exist in relation to heart disease and errors are committed which we should all wish to avoid. Much as is known many cases are hard to make out and difficult to treat.

I propose to discuss a few of the questions which from

[illegible] Transactions, Nos. 345 to 350, vols. xxv., xxvii., xxix.,
[illegible] ription of the
[illegible] 'e ferens, 1727.

this opening, after the contents had been sponged out, the mucous membrane was examined systematically, that lining the anterior wall of the stomach being pressed into the opening from the front and that on the posterior wall being brought into view bit by bit by the fingers of the left hand, which were passed through the rent in the great omentum. The only part which could not be seen was the neighbourhood of the cardiac orifice, and this was brought into view without difficulty by means of a full-sized vaginal speculum passed into the opening. Two small superficial ulcers were discovered on the posterior wall, nearer the cardiac end than the pylorus. They were triangular in shape when seen through the speculum (this may have been due to tension upon their margins), with steeply cut edges, only involving the mucous membrane and bleeding freely when touched. Silk ligatures were passed in two directions underneath these ulcers by means of curved needles and tied so as to strangulate the base; and as nothing else could be found the wound in the stomach was closed by means of a double set of silk sutures, the sponges were withdrawn, and the abdominal opening was secured with silkworm gut. Recovery was uneventful except for the persistence of vomiting. This was very severe and very painful for the first 36 hours and continued once or twice a day for the first 10 days, when it ceased altogether. On one occasion, some days after the operation, a small quantity of blood was brought up, but it seems to have preceded the vomiting, and it was not certain that it came from the stomach. The patient was allowed to have peptonised milk and the yelk of an egg on the second day after the operation, but no solid food was given until the abdominal wound was completely sound. She left the hospital on Jan. 6th, 1900, when she was free from pain and sickness and had been on ordinary diet for some days.

CASE 2.—This was the case of a woman, 34 years of age, who was admitted into the London Hospital under the care of my colleague, Dr. F. J. Smith, on Feb 9th, 1900. The patient had vomited blood for the first time on Feb. 5th; the quantity was said to be half a pint. This was repeated on the same day, once again on the 6th, twice on the 8th, and once on the 9th, the quantity on some of these occasions being undoubtedly very considerable. The motions were black. There was no history of dyspepsia or of vomiting after food. There had been a certain amount of pain in the abdomen during the last fortnight, but it was vague and not localised, and was not made worse by food. The abdomen was not tender. The patient had never vomited blood before, but about a year ago her stools had been very dark for some days. She was much blanched and the pulse was 132. The day after admission the patient vomited again, bringing up 10 ounces of almost pure blood; and as it was clear that further delay would be dangerous Dr. Smith very kindly transferred the case to me. An operation similar in all essentials to that already described was performed on the evening of Feb. 10th. One very small bleeding point was found on the posterior wall of the stomach near the pylorus. It could scarcely be called an ulcer, but as the edges were ecchymosed and blood could be seen oozing from it it was sutured in the way already described. The wounds in the stomach and in the abdominal wall were closed with as little delay as possible and three pints of saline fluid were transfused into the median basilic vein. The patient vomited twice in the course of the night, bringing up a certain amount of coffee-ground material but no fresh blood. After that there was no further trouble. Owing to the great previous loss of blood convalescence was slow, but the patient rallied well as soon as she was placed upon ordinary diet, and she left the hospital four weeks after the operation.

CASE 3.—This case had a more chequered history than the other two. The patient was a man, 42 years of age, who had been an inmate of another hospital five years before, suffering from pain after taking food, vomiting, and loss of flesh. He recovered from this, and continued well until seven months before admission, when the old symptoms returned with, in addition, hæmatemesis and melæna. There was considerable tenderness and pain in the epigastrium, but no lump could be felt. Laparotomy was performed on May 29th, 1900, with the view of ascertaining whether there was a malignant growth. Nothing was found and the abdomen was closed. On recovering from the anæsthetic the patient began to vomit blood; and as this continued through the night without there being anything to account for it, on the following day the abdomen was re-opened, the stomach was drawn into the wound, packed round with sponges, and opened in the same way as in the two former cases. The stomach was very large, the mucous membrane was closely folded upon itself, and for a long time the source of the bleeding could not be found; but at last, on introducing a vaginal speculum, a large irregular surface upwards of one and a half inches in length was found at the cardiac end. Blood was pouring from it freely. The surface was covered with granulations and was very uneven. The edges were well defined but not steep. The muscular coat did not appear to be exposed. An attempt was made to ligature the tissues of the base by means of silk sutures passed underneath them from the mucous surface, but the silk cut through at once and only made the bleeding worse. After two or three attempts, as the patient's condition was not such as to make it advisable to prolong the operation more than was absolutely necessary, I determined to ligature the whole thickness of the wall. Fortunately, there were no adhesions on the serous side. A hand was introduced into the peritoneal cavity, the ulcerated portion of the stomach wall was invaginated into the interior by pressure applied upon the serous surface, and a silk ligature was tied as tightly as possible around the base of the invaginated cone. This controlled the bleeding at once. Three Lembert sutures were inserted across the puckered spot on the serous surface to safeguard it when the strangulated portion came away, and the incisions in the stomach and in the abdominal wall were closed as rapidly as possible. The patient was a good deal collapsed but rallied well. A small quantity of altered blood was vomited the same night, and the first stools that were passed were dark chocolate in colour, but there was no sign of any fresh bleeding, and everything went on well for 15 days. Then the patient was sick after taking some chicken, and two days later he was sick again, bringing up a considerable quantity of blood. This was followed by severe collapse, so that strychnia had to be freely given hypodermically. Three days later he was sick again, but brought up no more blood; and after that he began to improve rapidly. There was no more vomiting or pain on taking food. A fortnight later the patient was placed upon a diet containing minced meat, and a few days afterwards he left the hospital, apparently perfectly well. Whether the hæmatemesis a fortnight after the operation was due to the separation of the strangulated portion of the stomach wall or to the presence of another ulcer which had been overlooked at the time of the operation it is impossible to say, but the rapid recovery and the freedom from pain make me incline to the former view. Still, it must be remembered that ulcers are multiple in no less than 13 per cent. of the cases examined post mortem.

It has been estimated that hæmatemesis only proves fatal in 4 per cent., or at most in 5 per cent., of the cases in which ulceration of the stomach is diagnosed, and it might, therefore, be thought that such an operation as the one which I have described would be very rarely required. But though hæmatemesis may not actually prove fatal of itself it not unfrequently places life in serious danger and still more often it creates such a feeling of apprehension as to destroy all pleasure in life. It is not unreasonable, therefore, to think that if this operation could be shown to be unattended by any great amount of risk there are many people who would prefer the chance of an immediate and perfect cure to months, and even years, of comparative starvation with the possibility of sudden death always before them and at best a doubtful hope that recovery will ever be perfect. I am aware that the mortality attendant on operation for acute hæmorrhage has been estimated by Mr. Mayo Robson in his recent lectures at 64 per cent., but these figures admit of an obvious explanation and they merely illustrate the fallacy of statistics. As a matter of fact, the stomach, owing to the thickness of its coats, stands suture better than any other portion of the digestive tract, and if only cases are operated upon at a sufficiently early period, and not when they are *in extremis* or when the wall of the stomach has become extensively thickened and adherent, there seems to be no valid reason why the mortality should be greater than that of interval operations in cases of inflammation of the appendix. I must not be understood to suggest operation in cases in which the amount of blood lost is not sufficient to be serious or in which there has been only a single attack of hæmatemesis; but when the bleeding returns more than once and is either so profuse as to place life in immediate peril or so continuous as to threaten a condition of dangerous anæmia, operation, with the view not only of stopping the bleeding once for all but of getting rid of the ulcer and of doing away with the possible risk of perforation, seems to me to offer a far better prospect than persistence in a form of treatment which has been tried and so far has not succeeded.

There are two points which deserve a certain amount of consideration. The first is the difficulty of finding the spot from which the bleeding comes. The second is the difficulty of dealing with it when it is found. There are two cases on record in [illegible] d for hæmatemesis and [illegible] been ascertained. In one of these an ulcer, described as being larger than a franc piece, was found later at the post-mortem examination. That it was overlooked is not a matter for surprise if it is taken into consideration how difficult it is, especially in an operation which may have to be performed against time, to inspect and to examine thoroughly the whole mucous membrane of the stomach through a narrow opening in its anterior wall and to unfold and open out every recess so as to make sure that no erosion can be overlooked In the other case no ulcer at all was found. This case does not stand alone; there are a considerable number of cases on record in which hæmatemesis has occurred and has proved fatal, not only without any ulcer, but without any lesion that could be detected post mortem, and this perhaps constitutes the greatest difficulty of all

A good many of these cases have occurred after abdominal operations. One case, following an abdominal exploration, happened in my own wards only a few days before my third case of hæmatemesis was operated upon The patient was a man, only 23 years of age. The complaint was carcinoma of the pelvic peritoneum. The operation was merely an incision two inches in length in the left iliac fossa and did not take more than 10 minutes altogether. The anæsthetic, which was A.C.E., was taken perfectly. The next morning, however, hæmatemesis set in and continued with such severity that death ensued within 48 hours, and at the post-mortem examination no lesion of any kind connected with the stomach could be found. There was no secondary deposit or ulceration. It is quite true that in these cases the other symptoms of gastric ulcer are usually wanting, but so they may be in the more acute forms of ulceration, the very cases in which hæmatemesis is most likely to occur and in which gastrotomy would prove of greatest service. In reference to this point I do not feel at all sure that the ulcer would ever have been discovered in my second case if the examination had been made post mortem and not during life In spite of the patient having been reduced by the loss of blood to such a condition as to render transfusion imperative the ulcer was so insignificant that it was only detected after a long search. It was a mere erosion and did not deserve to be called an ulcer, and I cannot help thinking how easy it would have been to have overlooked it altogether if the inspection had been made after death, when there was no blood escaping from it to act as a guide.

The question, I suppose, really turns upon what is meant by the phrase "ulcer of the stomach." Hæmorrhage may, of course, take place from the mucous membrane of the stomach, as it [illegible] without ulceration, and it [illegible] to prove fatal; but it is [illegible] t it can take place to this extent without a superficial rupture or erosion of some kind—so slight, perhaps, as to be scarcely perceptible post mortem when the bleeding has ceased, but distinct enough to localise the source of the hæmorrhage if seen during life and so to bring it within the range of surgical treatment. Certainly, given another case similar to the one which I have mentioned above of apparently [illegible] in spite of all ordinary [illegible] fatal, I shall not hesitate [illegible] eding comes, even if this does involve opening the abdomen a second time and incising the wall of the stomach.

The other difficulty to which I alluded is the treatment of the bleeding point when it has been found. All sorts of methods [illegible] a good many have been tried—exc[illegible] of the artery on one or both side[illegible] ace, the actual cautery, strangulat[illegible] sutures, ligature of the whole thickness of the wall drawn up into a cone, gastro-enterostomy, pyloroplasty, and even pylorectomy. Clearly no single method is available or even possible for all cases. Excision is probably the ideal one, but in any given case it is impossible to form a decision until the ulcer is seen and all the conditions are known. The locality of the ulcer, its size and dept[illegible] much inc[illegible] sions to neighbouring organs, all require to be taken into consideration, and it very rarely happens that anything but the most general information can be obtained about any of these points before the abdomen is opened. Even the character of the hæmorrhage gives no clue, for apparently it may be equally severe and dangerous, whether it is arterial, venous, or even capillary.

Wimpole street, W.

THE PROPHYLAXIS OF MALARIA AND THE DESTRUCTION OF MOSQUITOES IN THE ISLAND OF ASINARA.

BY PROFESSOR C. FERMI

AND

DR TONSINI.

(*Specially translated for* THE LANCET *from the "Annali d'Igiene Sperimentali,"* Vol. X., *Fasc. II., 1900.*)

As our readers may be aware, the island of Asinara, which is situated to the north of Sardinia, has the form of a figure 8 and it is only inhabited by convicts and by the staff of the lazaretto and of the penal colony. Before beginning the prophylactic experiments against malaria we considered it essential to study the topography of the island minutely and to compile a map indicating the following points: (1) the localities which are affected by malaria of grave or of mild type; (2) the localities where water exists either perennially or temporarily, in a standing condition or running, potable or brackish; (3) marshes, cisterns, pools, wells, tubs, &c.; (4) the superficial area and depth of the various collections of water; (5) the temperature, flora (lemna), fauna (amphibians, aquatic insects, &c.), of such collections; and (6) the presence of larvæ of the culex and of the anopheles We were careful to compile the chart in the æstivo-autumnal season of the year.

The following are the results of our investigations. In the whole island of Asinara we found 11 malarious localities, six of which, with severe types of fever, lie in the southern portion facing Sardinia—namely, at Sant' Andrea, Castellaccia, Fornelli, Punta Lunga, Stagno di Santa Maria, and P Pagliaccia, and the remaining five, with mild forms of the disease, in the northerly part—namely, at Cala d'Oliva, La Reale, Secondo Periodo, Campo Perso, and Tumbarino. The total superficial water area in the malarial season varies between 600 and 700 square metres, only one-fifth of which belongs to the northern half of the island, while all the rest lies in the southern portion, which is much more malarious. With regard to these 600 or 700 square metres it is to be noted that about one-half consists of perennial collections of water, including about 400 square metres of marshes, of which there are nine—namely, one of 10, two of 13, two of 20, one of 30, one of 40, one of 100, and one of 200 square metres; about 50 square metres are formed by 36 wells, half of which depend on springs; there are besides one deep well, 13 tanks with a superficies of 20 square metres, and seven tubs with four or five square metres of surface. We found larvæ of mosquitoes in nine collections of water and none in the other nine All the seven tubs and a drinking-tank contained a great number of larvæ; in the tubs especially were numerous larvæ of anopheles, and in two of these filled with soapsuds we found many eggs of the culex. These last, though not yet hatched, were still alive, for they speedily emerged from the egg when placed in ordinary water, otherwise the larvæ did not live for more than 24 hours. We found aquatic insects in 506 specimens of water, and amongst [illegible] other coleoptera, and [illegible] the mosquito. [illegible] assed to the prophylactic experiments.

A *Destruction of the mosquito in its larval stage.*—The destruction of the larvæ [illegible] water throughout the i[illegible] method described in a [illegible] *Sperimentali*' (fasc I., 1900), entitled "The Liberation of a City from Mosquitoes" The process was commenced in June and was continued until the end of November. The drinking-tanks and the tubs containing larvæ were completely emptied every 10 or 15 days, good care being taken that the water was rapidly absorbed by the soil so as not to allow of the development of the pupa, which may take place even on moist ground.

B. *Destruction of the mosquito in its adult stage.*—This was done by means of a mixture of powder of pyrethrum, chrysanthemum, valerian, &c., and with the zanzolina of Celli and Casagrandi, and, in the dormitories of the convicts when we had nothing better, by chlorine gas evolved from chloride of lime by sulphuric acid.

C. *Protection of habitations against the mosquito.*—We instituted these experiments in the convicts' dormitories which are situated in the southern part of the island looking towards Sardinia. The two dormitories, which are of rectangular form and one storey high, are built side by side; each is provided with one door and from 10 to 12 windows placed at a height of one and a half metres from the ground, and each accommodates about 40 convicts The means used for protection against the mosquitoes consisted of strong resistant muslin tacked over frames fitted on the windows. Every morning regularly on the convicts leaving, any mosquitoes which might have found their way into the dormitories were destroyed. When the insecticide employed was chlorine the windows were opened after an hour or two, so that on the return of the convicts the dormitories might be quite free from both gas and mosquitoes. By a daily inspection of the cells and by questioning the convicts and guards we assured ourselves that the experiments were going on satisfactorily.

The results obtained were as follows. 1. The anopheles was almost never found in any of the dormitories, and the culex pipiens was much diminished in comparison with former years. 2. No case of primary malaria originating in the island was observed, for of the nine cases which occurred two came from Castiadas, one from Isili, and six were relapses. In the preceding year there had been 99 cases, of which 40 had been contracted in the island.

The island of Asinara both by its position and by the small quantity of water which it contains, by the absence of streams, and by the ease with which its convict population can be subjected to experimental conditions, lends itself in a unique and peculiarly suitable way to these experiments for the prevention of malaria, experiments which we mean to continue in the present year with the full confidence of then being able to present the first example of an entire country being freed from malaria by the destruction of the malaria-producing mosquitoes infesting it, and by the protection of the inhabitants against their infecting bites.

OPERATION v. TRUSS IN THE INGUINAL HERNIA OF CHILDHOOD.[1]

BY R HAMILTON RUSSELL, F.R.C.S. ENG.,
SURGEON TO THE MELBOURNE HOSPITAL FOR SICK CHILDREN.

AMONG the rather numerous contributions that have been made to the literature of hernia during the year 1899 there have been two that have come under my notice dealing especially with the questions propounded by the occurrence of inguinal hernia in children. At the Portsmouth meeting of the British Medical Association the subject was dealt with by no less eminent and experienced an authority than Mr. John Langton. I hope I may be pardoned for my undoubted presumption in placing in juxtaposition to Mr. Langton's authoritative utterance a paper read before the Surgical Section of the Inter-colonial Medical Congress of Australasia and published in THE LANCET of Nov. 18th, 1899, p. 1353, by myself, and I must in extenuation state the reasons that have impelled me to this course. In the first place I must point out the direct, I may even say the extraordinary, antagonism between the views held by Mr. Langton and those to which my own experience and reasoning have led me as set forth in the above-mentioned paper. The principles underlying the treatment of inguinal hernia in childhood that Mr. Langton advances as the result of his mature experience, together with the pathological reasoning that he incidentally introduces, display no new features. On the contrary, they constitute simply a confirmation of principles and methods that are time-honoured, so that I feel almost guilty of sacrilege in venturing to bring them into serious question. The effect of Mr. Langton's weighty pronouncement will without doubt be to disarm any lurking suspicions there may have been as to the rectitude of our established courses in dealing with hernia in childhood; my desire, on the contrary, is to re-arouse such suspicion and to stimulate rebellion. Mr. Langton's views may be stated as follows:—1. Hernia in a child may almost always be cured by a truss if sufficient skill and care be exercised, and some details are given as to the relation between the length of time the truss should be worn and the age of the patient. 2. Operation is, therefore, very rarely called for in children, and as additional reasons telling against operative treatment it is stated that the anatomical structures in the case of children are ill-suited to manipulation and that the sac is often difficult to find. 3. As to the mode by which continuous retention of the hernia brings about a "cure," this is not very clearly set forth, but it seems to me that a sort of veiled countenance is accorded to the popular superstition that the truss in some mysterious way causes obliteration of the sac through pressure. Now the whole argument hangs upon the truth or falsity of the proposition that inguinal hernia is curable in the large majority or even in a reasonable percentage of cases by the use of a truss, as Mr. Langton, in common with almost all authorities, states to be the case. To this proposition I must, with all deference, oppose a direct negative, and I cannot make it too sweeping and too strong. I say simply that (excluding very young infants) the use of a truss never cured a hernia yet and never will. To be explicit, by "curing" I mean not merely causing the hernia to keep up for an indefinite period—the essential feature of the "cure" must be the abolition of the hernial sac. The term "cure" is a misnomer when applied to any method of treatment that causes the hernia to disappear but leaves the sac still existent and ready at any time during the patient's life to receive the hernia again. What, then, is the explanation of the extraordinary error that has permeated the theory of inguinal hernia? Simply this: the remarkable mechanism of the inguinal canal has not been rightly understood and its significance has not been fully grasped; above all, the great fact of inguinal hernia has not been recognised—viz., that there is only one fundamental cause of oblique inguinal hernia, and that cause is the presence of a congenital sac in the inguinal canal. This statement is equivalent to a denial of the existence of any such affection as acquired oblique inguinal hernia. The practical significance of this fact and how far-reaching its effect must be upon the whole attitude of surgical science in respect of inguinal hernia is, I venture to say, a thing not generally apprehended. I have already dealt with this subject in another paper with considerable fulness, and I would ask any readers who do me the honour of considering this paper worthy of perusal to refer back to that paper, which is to be found in THE LANCET of Nov. 18th, 1899, p. 1353. On the present occasion I do not propose to recapitulate all the arguments that have already been adduced, but I think I see sufficient reason for telling the story again, and this time I shall treat it in a somewhat different way.

In my former paper I dealt with the subject of the etiology and treatment of inguinal hernia in the young in the customary formal way, beginning with the anatomy and physiology of the inguinal canal, passing onwards by stages of pathological reasoning and clinical observation to certain conclusions as to the right treatment of inguinal hernia in children—conclusions which are diametrically opposed to those that have always been and still are regarded as unimpeachable. On the present occasion I shall proceed in the reverse order, commencing with the operative treatment, deducing from the results obtained important conclusions as to the etiology of inguinal hernia, and finally the conclusion that the presence of a congenital sac is the sole cause of inguinal hernia, and that operative removal of the sac is the only treatment that is surgically sound. The adoption of this order in the treatment of the subject has the further advantage that it coincides with the order in which the evidence presented itself to me, and it will probably prove a convenient and effective plan for me to sketch briefly the history of my own experience in the treatment of inguinal hernia in childhood.

---

[1] The arguments employed in this paper are not meant to apply to the case of very young infants.

It is now nearly five years since I first operated on a child by Bassini's method and I can remember my dissatisfaction at the end of the operation. I had incised the external oblique aponeurosis which was quite unnecessary; I had found the sac projecting through a relatively small opening,
bounded b
below, and
stitching th
happily no
when carric
integral factor in the permanent prevention of hernia. In a certain class of cases—viz., old-standing hernia where the inguinal opening is widely stretched and the musculature extensively damaged—suturing of the walls of the canal after Bassini's method is possibly both rational and proper when performed with full understanding of the purely temporary object the sutures are intended to serve, but as a routine m
manently fortifying
the hernia the mere
Since that first case I have never used any sutures whatever to the walls of the canal in children. I now began to operate with rapidly increasing frequency and was very soon struck with the fact that the inguinal herniæ of boys are with the rarest exception all alike, in that they are formed by the descent of bowel or omentum into an unobliterated portion of the processus vaginalis; while there is, I believe, no exception to the rule that the sac is congenital. Thus I have now operated 80 times, and of these I have no doubt
that 79 were funicular (either total or partial) a
was a non-funicular congenital sac. If I am ask

sacs by means of a host of coinciding points of e
Thus a certain number bear the unmistakeable b
funicular origin in a variety of markings, annular
ings, &c., due to attempted obliteration at those p
by some evidence of obvious relationship with the tunica vaginalis, and so on; while those that do not offer any such direct evidence will be found to be anatomically identical with those that do in their relationship to the cord. That all the sacs are of congenital origin and that none of them are acquired is furthermore proved by the results of operation. Now, if a surgeon operates on a case of inguinal hernia and he opens up the canal and removes the sac and fixes the stump somewhere and puts the cord in a position which he considers an improvement on that chosen by Nature, and he carefully stitches up the canal and keeps the patient in bed for six weeks and the hernia does not recur,—having done all these things he does not really know what the result is due to and he will therefore have learnt nothing as to the original cause of the hernia. His position will be that of the apothecary who puts into a "mixture" a drug for each ailment that he thinks his patient *may be* suffering from, so that when the patient recovers he is no nearer to a correct diagnosis, being unable to tell which, if any, of the drugs has effected the good result. If, on the other hand, the surgeon operates on a case of inguinal hernia, and he does nothing except ligature and remove the sac at the level of the internal ring, and he lets the patient get up in 10 days,—if then the hernia does not recur he knows exactly what he has done to cure the hernia and there can be no possible doubt as to the original cause of the affection. Simple removal of the sac having cured the hernia the conclusion that the sac must have been the sole cause of the hernia is irresistible, for had there been any factor other than the presence of a congenital sac concerned in the production of

have found that the whole number are caused by the presence of a congenital sac. I find, further, that of the 80 congenital sacs 79 were of funicular origin. It is, I submit, inevitable that from these facts we should deduce the following conclusions:—1. Inguinal hernia in young subjects is caused by the presence of a congenital sac and there is no other cause. 2. The sac is in the vast majority of cases an unobliterated portion of the processus vaginalis. 3. Acquired oblique inguinal hernia in the young has no existence in fact. 4. Seeing that oblique inguinal hernia cannot occur in the absence of a congenital sac there can be no recurrence after the sac has been efficiently removed. These conclusions have yet, however, to be passed through a mill of very exacting criticism, and on their behalf many objections, at first sight very formidable, have to be met. The first objection that will be advanced will be on the score of sheer *primâ facie* probability. Is it reasonable, it will be urged, to deny to the inguinal canal of all places the capability of becoming the seat of acquired hernia? Acquired hernia is common elsewhere, notably in the femoral canal, and also in the form of direct hernia through the external ring. It is liable to occur also with inconvenient promptitude in any portion of the abdominal wall that may have been incised. Is it likely that the

scrutiny of the mechanism of the inguinal canal. I must ask pardon for saying that a clear idea of this mechanism is by no means universally displayed by the multitude of surgeons who have written upon hernia, and even Lockwood, whose writings on this subject are surely of surpassing excellence, does not appear to me to make quite as much of it as I
made. I am not aware that
described quite so clearly as they are set forth in my own paper to which allusion has been made, and as I have nothing to alter in that description I will ask permission to reproduce it.

springs from Poupart's ligament, that the conjoined tendon fortifies the inner portion of the canal, and that the whole region receives support from its covering of external oblique aponeurosis, but the

abdominal viscera and a *vis a tergo* is required before any viscus can be

This, then, I consider the complete answer to the argument as to the improbability of the inguinal canal being immune from liability to become the seat of an acquired sac, based on the analogy of hernia occurring in other situations. There is no real analogy whatever. This remarkable automatic, self-regulating sphincter mechanism is the peculiar possession of the inguinal canal; it completely destroys any semblance of analogy with any other of the seats of hernia, and intelligent contemplation of it will go far towards converting our views as to the probability in favour of the inguinal canal being sometimes invaded by an acquired sac into something very like a dead certain conviction that in the face of such efficient protection it never can be so invaded.

The second objection that has to be met deals with my fourth proposition, which is to the effect that hernia cannot recur after the sac has been efficiently removed. To this statement will be opposed the seemingly unanswerable argument that hernia has recurred often enough after operations in which removal of the sac was a feature. I have

TABLE OF 15 CASES OF DIPHTHERIA TREATED WITH SALINE INFUSIONS.

Case.	Age.	Antitoxin.	Saline infusion. Injections.	Saline infusion. Amount.	Remarks on case.	Complications and sequelæ.	Number of days in hospital.	Result.
1	5½ years.	12,000 units.	4	20 ounces.	Great fœtor with spreading membrane.	Suppression of the urine.	3	Death.
2	4 ,,	9,000 ,,	3	15 ,,	Profuse epistaxis.	Scarlet fever 18 days after admission.	98	Recovery
3	4½ ,,	15,000 ,,	2	25 ,,	Very severe attack with "bull neck."	Macular rash on the fifth day; paresis of the lower limbs.	73	Recovery.
4	1½ ,,	12,000 ,,	3	26 ,,	Extreme restlessness; sleep after infusion.	Abscess on the seventh day; rash on the third day; cardiac vomiting and failure.	17	Death.
5	5 ,,	15,000 ,,	4	36 ,,	Much discoloured membrane; great swelling.	—	Transferred to the Convalescent Hospital.	Recovery.
6	2 ,,	9,000 ,,	3	20 ,,	Hæmorrhagic.	—	2	Death.
	5 ,,	18,000 ,,	2	20 ,,	—	—	3	Death.
8	2½ ,,	15,000 ,,	1	9 ,,	—	—	1	Death.
9	4 ,,	12,000 ,,	2	22 ,,	Profuse epistaxis continuing till death.	—	7	Death.
10	9 ,,	15,000 ,,	2	24 ,,	Great restlessness relieved by infusion.	Broncho-pneumonia on the sixth day.	8	Death.
11	7 months.	9,000 ,,	2	6 ,,	Faucial and nasal.	—	52	Recovery.
12	3 years.	15,000 ,,	3	20 ,,	Much membrane; severe continuous epistaxis.	Cardiac vomiting from the fifth to the eleventh day; diaphragmatic and laryngeal paralysis on the thirtieth day. Paresis of the lower limbs.	63	Recovery.
13	4 ,,	9,000 ,,	3	33 ,,	Much membrane spreading; great fœtor.	Ocular paralysis on the thirty-fourth day.	Transferred to the Convalescent Hospital.	Recovery.
14	2 ,,	9,000 ,,	4	24 ,,	Spreading discoloured membrane.	Rash on the second day; general paresis.	62	Recovery.
15*	6 ,,	15,000 ,,	2	23 ,,	Much membrane; fœtor; delirium; hæmorrhagic.	Abscess on the eighth day. Cardiac vomiting from the thirty-second to the forty-first day. Diaphragmatic paralysis on the thirty-fifth day; general paresis.	98	Recovery.

* This patient was under the care of my colleague, Dr. Densham, after the first week. During the vomiting stage she was given saline infusions on several occasions with marked benefit.

15 patients seven died, while eight recovered after a convalescence more or less eventful. Of the seven fatal cases six patients died during the acute stage. In three cases the patients developed the usual symptoms of heart failure; one patient died on the seventeenth day, the other two recovering after a prolonged period, during which paralysis of the diaphragm occurred.

Of course no definite conclusion may be drawn from the results of only 15 cases, although these were chosen from a large number of admissions as being of the severest type and therefore most likely to develop cardiac paralysis. Nevertheless this treatment appears so far to have some influence in diminishing both the frequency of onset of symptoms of heart failure and their severity when they do occur. Further experience is, however, necessary before one may dogmatise.

As in the case of antitoxin treatment the results will probably be the better the earlier the patient is admitted to hospital, and on this account I have endeavoured in all cases to complete the infusion by the second day after admission.

Two of the patients developed an abscess at the site of injection. This, though a high rate, must be considered, I think, as more or less accidental, and in dealing with a large number of cases the occurrence of an abscess after saline infusion would be probably not more frequent than is the case after injection of antitoxin alone. In neither instance did any ill effect follow and after evacuation of the pus healing rapidly took place.

My best thanks are due to Dr. Birdwood for permission to publish this paper and to my colleague, Dr. W. A. Densham, for permission to make use of Case 15.

Hither Green, S.E.

THE VALUE OF ANTI-STREPTOCOCCIC SERUM.

BY GERALD S. WALTON, M.B., C.M. EDIN.

A RECENT number of THE LANCET contains some depreciatory remarks about anti-streptococcic serum by Dr. Ranken Lyle.[1] Scepticism is a virtue, but it may be carried to an extreme, and what I fear is that some medical men after reading Dr. Lyle's paper may put its scepticism into practice and never use the serum again. I venture to think that such ultra-rationalism will every now and then meet with its own reward in the shape of a lost case. I have not the slightest hesitation in saying that in the two cases which I am about to describe the result was no mere coincidence, such as Dr. Lyle wishes to suggest, but that it was a genuine remedial action on the part of the serum only.

CASE 1.—A married woman, aged 20 years, a primipara who had been anæmic and ill-looking even before the birth of her child, was confined easily on August 10th, 1900. There were shock and depression of spirits and slight rise in the pulse and the temperature almost from the start. There was sepsis from the third day, when a small fœtid clot was passed. The milk was suppressed and the infant had to be weaned. The lochia were much too small in amount and were rather putrid, and the womb was flabby and tender. By the fifth day the temperature was 101·5° F., the pulse was 130, and the patient was weak and yellowish in colour.

---

[1] "Puerperal Sepsis," THE LANCET, Sept. 29th, 1900, p. 925.

by a slight reaction, and on the next morning there was a distinct though slight improvement in the pulse, in the temperature, and in the general condition, which was [illegible]

[illegible] occurred after [illegible] time the im- [illegible] days and the [illegible] dropped to 100°. A relapse then set in, and by the sixteenth day the temperature gradually went up to 103°. On the next morning 10 cubic centimetres of the serum were injected into the right arm, the temperature then being 101·5°. In the evening a pleuritic catch was complained of and was detected in the right lung and a little [illegible] The patient's temperature was [illegible] the same on the next morning [illegible] sodium salicylate. This caused profuse sweating and a rich crop of sudamina and brought down the temperature to 99·4°. The patient was then put on a mixture containing sodium salicylate and she was convalescent by Sept. 4th.

CASE 2.—The patient was a woman, aged 30 years, who was, curiously enough, of the same name as the patient in Case 1 but was not in any way related to her. She had been subject to "[illegible]" [illegible] e had another attack after [illegible] the case and the appearar[illegible] icate that she was right. She was very weak. On the second day of my attendance her temperature was 100° F. and her pulse was 108. There was a nasty dark slough which involved the tonsil, the uvula, and the neighbouring parts. The patient's general condition seemed precarious in the extreme and a swab and a bit of the slough were sent to the Jenner Institute of Preventive Medicine for examination; but without waiting for the report, as I judged the case to be septic if not diphtheritic, I injected 10 cubic centimetres of anti-streptococcic serum. [illegible] the pulse [illegible] although [illegible] the patie[illegible] temperat[illegible] strength, and her general condition was vastly improved. A report from the Jenner Institute came that day that diphtheritic bacilli had been found in the materials submitted for examination and she was consequently removed to the isolation hospital, where she continued to make satisfactory progress.

The serum used on all these occasions was supplied by Messrs. Burroughs and Wellcome. It is true that the patient in Case 1 eventually got well on sodium salicylate and that there was apparently a connexion between the third injection of anti-streptococcic serum and the smart attack of dry pleurisy which occurred, yet I was quite satisfied with the effect of the serum on the fifth and sixth days and I blame myself for not using it again till the sixteenth day. With [illegible] who was kind enough to [illegible] me out that the effect of [illegible] Even allowing that she was left in a weak state and that after leaving my hands she was further [illegible] days, I maint[illegible] which the c[illegible] Diphtheria in [illegible] I would suggest that in all cases a preliminary dose of anti-streptococcic serum should be given. I cannot think it judicious that such a powerful remedy—call it "tonic" if you will—should be lightly and flippantly cast aside.

Sutton, Surrey.

HOSPITAL SATURDAY.—Hospital Saturday was observed in London on Saturday for the twenty-seventh successive year, and special collections were made in many thousands of business houses and workshops on behalf of the hospitals and dispensaries. The method of street collection has been abandoned, but the regular "penny-a week" collection in the industrial establishments will be continued until the end of December, by which time it is hoped that the total for the year will not fall short of that raised in 1899—viz., £20,013. The result of Saturday's collection will be announced at the annual general meeting of the association to be held at the Mansion House on Oct 27th.

A CASE OF ANTHRAX; EXCISION OF PUSTULE; RECOVERY.

BY EDWARD C. [illegible]

BACTERIOL[illegible]

I AM reminded by the case narrated by Dr. E. F. M. Neave in THE LANCET of Oct. 6th, p. 1012, of a somewhat similar one which occurred in my own practice.

I was consulted at 2 P.M. on Oct. 22nd, 1898, by a man whose business involved the handling of imported hides as received. He had upon his neck over the sterno-mastoid a swelling of a very suspicious appearance, dusky red, with a central depression surrounded by vesicles of small size, which he had noticed that morning for the first time. His temperature was above 102° F. and the appearances were altogether so unsatisfactory that I asked my friend Dr. C. Wenyon, who had seen several cases of anthrax in [illegible] me, and he was incline[illegible] so fully on the followin[illegible] extent increased in si[illegible] 104°. The patient bein[illegible] willing to submit to ope[illegible] three-quarters of [illegible] and removing everything down [illegible] and was then thoroughly cauter[illegible] undisturbed till the slough separated. The temperature fell on the same evening to 99·4°, and was normal on the following day, after which recovery was uninterrupted. The serum con[illegible] few bacilli, quite like those of anthrax, but I [illegible] yet had time to examine the pustule. Apart, [illegible] its perfectly typical appearance, a drop of [illegible] grees in the temperature within six hours [illegible], and the fact that the patient remembered having had a pimple on his neck, which he had scratched with his nail whilst engaged in examining hides, seemed to render any doubt of the diagnosis untenable. It seems a pity that the same treatment was not tried in the case which suggested this note.

No remedy is known to have any certain effect in this disease, whilst it seems probable that the toxic symptoms, in the human subject at least, [illegible] from a limited [illegible] *[illegible] facie* the trea[illegible] similar case I should certainly do the same again, except that I should do it at once

A RARE CASE OF FRACTURE OF THE OS CALCIS BY MUSCULAR FORCE.

BY ROBERT THOMSON, M.D., M.CH. R.U.I.,

HONORARY SURGEON TO THE MARGATE COTTAGE HOSPITAL.

A WOMAN, aged 57 years, stood on a Windsor chair to reach some china from a cupboard. She had the china in her hand and was turning round to place it on a table close by when she got too near the edge of the chair, which capsized, and she was thrown to the ground. As her weight was overbalancing the chair her left foot, while remaining in contact with the seat, was forcibly and suddenly flexed. She was wearing a pair of ordinary [illegible] On examination some hours after [illegible] up the back of the left leg a [illegible] ankle. The tendo Achillis was felt ending in a hard moveable mass some five inches from the sole of the foot and between this mass and the os calcis was a considerable depression It was evident that the os calcis had fractured, the tendon remaining intact. The fragments could not be approximated. I cut down on the seat of the fracture and found that a piece of os calcis of about the size of half a walnut and corresponding to the area of insertion of the tendon had been wrenched off and drawn upwards. This could now, under anæsthesia, be easily brought down and apposed to the corresponding fracture surface on the os calcis. The fragments were retained in position by an encircling silver wire passed through the body of the os calcis and through the tendon at its attachment to the fragment. The wound healed by first intention and firm union of bone resulted. Free action of the joint was subsequently much delayed by an attack of melancholia, during which the patient would not leave her bed or permit of movements being made At the end of two and a half months, however, she could walk well.

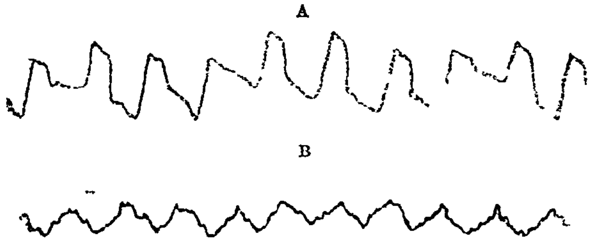
This patient presented no evidence of bone degeneration and had never sustained a fracture of any kind before. She was well nourished and had enjoyed good physical health. She is said to have had previous mental attacks. No obvious reason presents itself for the bone having fractured, instead of the usual rupture of the tendo Achillis under like circumstances, except it be the noticeable tendency of bone to fracture under slight provocation observed in some patients suffering from mental disease.

Margate

A POINT IN THE DIAGNOSIS OF ANEURYSM OF THE AORTA.

BY WALTER BROADBENT, M.D. CANTAB., M.R.C.P. LOND.

THERE are cases of aneurysm of the transverse part of the arch of the aorta which present as a slight pulsation in the second left intercostal space near the sternum before they have involved the recurrent laryngeal nerve, or the aorta may be pushed forward by an aneurysm of its posterior wall and give pulsation in this space. There are also cases where old phthisis of the left lung has caused exposure of the heart sufficient to give pulsation in the second left space. In both conditions the second sound is louder than normal over the pulsating area and it is difficult to make out any diastolic shock in the early pulsation of an aneurysm, though as a rule it is easy to distinguish the cardiac pulsation, since the whole surface of the heart is usually exposed and pulsation is continuous down to the apex beat. If a tracing of the pulsation be taken by a Marey's sphygmograph any doubt is at once cleared up, the arterial character of the tracing marking an aneurysm. The accompanying tracing (A) was taken from a man who had a cough and diminished air entry into the left upper lobe, and it was thought that he might be the subject of early phthisis. Subsequent paralysis of the left vocal cord and increase in the pulsation confirmed the diagnosis of aneurysm. A tracing (B) of the cardiac pulsation in the second left space from a case of old phthisis is added for comparison.



A, Pulsation in the second left space Small aneurysm of the transverse part of the arch B, Pulsation in the second left space in a case of old phthisis

Brighton.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of the society was held on Oct. 10th, the President, Mr. Christopher Heath, being in the chair. One new member was elected and the deaths of two members were reported. There were no fresh applications for grants. The death of a widow was announced. Applications for grants were read from the 47 widows, 12 orphans, and six recipients from the Copeland Fund now on the funds of the society, and it was resolved that £1187 10s. be given at the next court. It was also resolved that Christmas presents be given this year amounting to £531—£10 to each widow, £3 to each orphan, and £5 to the five receiving extra grants from the Copeland Fund. The expenses of the quarter were £61 5s.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

A CASE OF HYDATID CYSTS OF THE LIVER RECURRING AFTER AN INTERVAL OF TEN YEARS IN THE PLEURAL AND PERITONEAL CAVITIES; DRAINAGE; RECOVERY.

(Under the care of Dr. EUSTACE SMITH and Mr. J. F. C. H. MACREADY.)

ALTHOUGH hydatid disease is not so frequently met with in this country as in some other portions of the world, such as Australia, yet it is sufficiently common to cause us frequently great difficulties both in diagnosis and treatment The following case illustrates the value of the bile test when applied to the hydatid fluid as an indication that the cavity opened communicates with the liver. Even when it is difficult or impossible to obtain the bile reaction crystals of bilirubin may be found in the hydatid fluid by the aid of the microscope; this fact was first pointed out by Bristowe.[1] For the notes of the case we are indebted to Dr. J. G. Emanuel, pathologist to the General Hospital, Birmingham, and late resident medical officer City of London Hospital for Diseases of the Chest, and for a careful record of the clinical history to Dr. O. K. Williamson.

A married man, aged 24 years, was on May 11th, 1899, admitted into the City of London Hospital for Diseases of the Chest, under the care of Dr. Eustace Smith. The patient was suffering from shortness of breath which had been coming on and gradually getting worse and worse for about five weeks. Five weeks before his admission while at work the patient was seized with a sharp pain in the middle of the abdomen. As a means of getting relief he took some tea but vomited immediately and he then went home and from that day onwards had done no work, having felt too weak and his breath having been too short. For two weeks before admission he had had pains in the right side of his back. The past history of the patient showed that on the whole he had enjoyed good health but that on two occasions (July, 1888, and October, 1889) he had been an in-patient at St. Bartholomew's Hospital and that on each occasion he had had a hydatid cyst of the liver incised and drained. The patient had two abdominal scars (one in the right vertical nipple line and the other in the epigastrium a little to the right of the middle line) bearing testimony to the statement, and subsequent inquiry at St. Bartholomew's Hospital corroborated these facts. The first operation was performed 11 years ago (in July, 1888) and the second operation a year later (in October, 1889). At each operation a hydatid cyst with daughter cysts was found, incised, and drained. After the second operation the patient left the hospital (in December, 1889) and had enjoyed good health since till five weeks before his admission to the hospital.

On admission the patient was found to be a pale, thin, red-haired man, sitting up in bed with a good deal of dyspnœa and the alæ nasi working. The pulse was 120, the respirations were 36, and the temperature was 102° F. The physical signs pointed to a large amount of fluid in the right chest; the heart was displaced outwards to the left (the maximum cardiac impulse being in the fifth space and in the anterior axillary line) and the liver was displaced downwards (the lower edge being three inches below the costal margin in the right vertical nipple line). The left lung was clear except for a few scattered sibilant rhonchi The heart sounds were normal. The urine was free from albumin. In the abdomen there was bulging of the right hypochondrium corresponding to the displaced liver. The tongue was clean, the appetite was poor, [illegible] The patient had been sleeping badly previously to his admission.

---

[1] Transactions of the Pathological Society of London, vol. iv.

On the evening of the patient's admission (May 11th) an exploring needle was put into the right chest in the eighth space in the scapular line and a syringeful of quite clear greenish yellow fluid loaded with albumin was obtained. On the following day, the dyspnœa having shown no signs of improvement, the right chest was tapped at the site of the exploratory [illegible] used. Failing, ho[illegible] was resorted to and eventually there were drawn off 38 ounces of [illegible] gravity of [illegible] quantity of [illegible] ent which [illegible] pus cells, granular débris, and cholesterin. No hooklets were found. The aspiration gave marked relief to the patient and he passed a good night. On the next morning (the 13th), however, he had a rigor, the temperature rising to 104·2°. On the 14th the evening temperature was 103·8° and as the patient showed evidence of sepsis it was decided to resect at the site of the aspiration puncture and to drain the pleural cavity. On the morning of the 15th the patient suddenly coughed up in the course of a few minutes about eight ounces of offensively smelling purulent greenish yellow fluid. Up to this date he had only had a slight cough accompanied by a little mucoid expectoration which had not attracted much attention, but from this time onwards the cough became troublesome and the expectoration purulent, considerable in amount, and offensive.

On May 16th the patient was anæsthetised and Mr. Macready resected a portion of the tenth rib in the right axilla. A needle put into the underlying membrane revealed pus. The membrane was then incised and there escaped a *large quantity of opaque greenish yellow* fœtid smelling purulent fluid together with some gas and a very large number of hydatid daughter cysts of various sizes. On inserting a finger into the now empty cyst a second tense membrane was felt presenting towards the wound and fluctuation could be obtained between a hand placed on the abdomen and a finger on this membrane. A needle inserted into this membrane again revealed offensive pus and so, having fixed the membrane to the edges of the wound with a couple of stitches, an incision into it was made and there escaped another very large quantity of fluid similar to that from the first cyst and containing similar daughter cysts in great numbers and of various sizes. The total quantity of fluid from the two cysts measured after the operation was seven and a half pints, but this did not express the total volume of the cysts, as a good deal of fluid was lost at the time of operating. The patient's breathing became easier almost immediately and the bulging in the abdomen caused by the liver disappeared. Two drainage tubes were inserted into the now empty cyst cavities. The wound was dressed daily and there was constantly a free discharge into the dressings. The cough remained troublesome and the expectoration free and highly offensive.

After this operation the patient in some respects improved and in others grew worse, for while his breathing became much easier (the maximum cardiac impulse being now in the fifth space in the vertical nipple line) his cough was more troublesome and distressing and his expectoration gradually increased in amount, rising to 10, 12, and 14 ounces per day, and was constantly offensive. His sleep also became seriously interfered with and he was obliged to assume the upright posture in bed both night and day. He was unable to lie on his back or on one side, for the instant that he attempted to do this a paroxysm of violent coughing would ensue accompanied by the expectoration of the offensive sputum. He was only able to sit straight up or to lean a little forwards and he accustomed himself to sleep with his head and arms resting on a cradle placed in front. The temperature remained high, rising to between 100° and 102° every night and the patient himself began obviously to lose ground. On four days (May 18th, 20th, 27th, and 29th) the sputum *was noted to contain some* bright yellow frothy material which gave the tests for bile. This led to the belief that the patient had another cyst in his liver which had ruptured through the diaphragm into the base of the right lung and was being coughed up. As the patient's condition was certainly getting worse further surgical help was indicated and it was decided to explore the liver in the hopes of finding this organ to be the seat of another cyst. [illegible] evacuation of the two pleural cysts) Mr. Macready performed a laparotomy and the liver was thoroughly explored and found to be adherent to the abdominal wall along the sites of the two old scars dating back to 1888 and 1889. In other respects, however, the liver appeared to be quite normal and so the wound was closed. While the patient was still under the anæsthetic a fluctuating swelling of about the size of an orange was palpated in the left iliac fossa. A needle inserted into this revealed offensive pus and accordingly it was carefully incised and about eight ounces of very offensive opaque brown fluid were evacuated similar in character to that evacuated at the previous operation from the pleural cavity but containing no daughter cysts. This abscess cavity was definitely shut off above by adhesions and certainly had no connexion with the liver. Below it extended downwards and inwards into the pelvis passing beyond the reach of the finger. This was undoubtedly a circumscribed suppurating hydatid cyst in the peritoneal cavity. Into this now empty cyst a drainage-tube was inserted. Subsequently it was dressed daily. The laparotomy wound healed by first intention, although it lay midway between two pus-discharging wounds—one in the right axilla where the pleural cysts were draining, and the other in the left iliac fossa where the peritoneal cyst was draining. The administration of the anæsthetic during the operation was rendered exceedingly difficult and unpleasant owing to the almost incessant coughing and expectoration of filthy yellowish offensive sputum.

The result of this operation was exceedingly unsatisfactory, because although the patient was to a certain extent relieved by the evacuation of the pent-up pus in the left iliac fossa the serious and distressing symptom which it was sought to relieve—viz., that of being unable to lie back or on either side without bringing on a violent paroxysm of coughing accompanied by offensive expectoration and obliging the patient to pass his days sitting upright and his nights leaning forwards on a cradle—was in no wise improved, and in addition he had a wound in the abdominal wall five inches in lengt[illegible] been explored, another wound i[illegible]er in the left iliac fossa, the two [illegible] The temperature continued to rise every evening to about 100° and the expectoration measured three, four, or five ounces of pus a day. Dr. Emanuel was confident, however, that the patient had another cyst communicating with his liver and his right lung, because he still continued at times to expectorate bile in his sputum. This hidden cyst further communicated in all probability with the thoracic wound which was draining the two cysts incised at the first operation on May 16th, as on many occasions the discharge from the wound contained bile and sometimes in considerable quantities. In the hopes of finding this troublesome cyst the right chest was explored with an exploring needle in different places without *success. On the afternoon*, however, of June 12th a long exploring needle was passed inside the wound in the right side of the thorax in a direction forwards and inwards and at a distance of five and a half inches from the surface of the chest, Dr. Emanuel came upon a hard bulging wall through which he pushed the exploring needle, using some considerable amount of force, and went into what gave the impression of being a cavity. From this he withdrew pus, which was offensive and similar in character to that which the patient had been expectorating. A director was then passed along the needle, and along *this director* a blunt-pointed bistoury, and a crucial incision was made in the wall of this the third thoracic cyst. 19 ounces of pus escaped and a drainage-tube was inserted. The patient immediately felt more comfortable and was able to lie down on his back and have a good night's rest; he had not been able to lie in a recumbent position for just three and a half weeks. After this he continued to sleep well and in a natural posture and coughed up no more of the yellowish offensive material till June 14th, when he again began to feel uncomfortable, not being able to lie down without the occurrence of a paroxysm of coughing. A careful examination showed that this was caused by the drainage-tube being out of its place, the hole in the cyst wall having closed up. The opening of this cyst was, it will be remembered, five and a half inches from the surface and it was very difficult to be sure whether the drainage-tube was in it or not. So on June 14th Dr. Emanuel again incised with a director and blunt-pointed bistoury and evacuated seven ounces of pus. The patient for the second time was immediately relieved and able to resume the horizontal posture with comfort. By this time the laparotomy wound over the liver was healed and the wound in the left iliac fossa was very small and discharging only a little pus every day. The thoracic wound [illegible] freely. On June 15th the patient got [illegible] onwards [illegible] to improve materially. His cough [illegible] became less troublesome and his sleep natural and sound. The temperature came down and he began to put on flesh. On the 27th it was again found necessary to in[illegible] cyst on account of the cough and [illegible] for two or three days, showing that the cyst was not draining properly, and on this occasion two ounces of pus escaped.

In the meanwhile the thoracic wound had been gradually healing and getting smaller and smaller, and it was evident that it was not sufficient for the thorough drainage of the third pleural cyst, the opening of which was five and a half inches from the surface. This opinion was supported by the facts that the patient's expectoration still amounted to six ounces of pus a day and that during the last week in June it had contained bile on two occasions. Accordingly it was deemed advisable to enlarge the thoracic wound and this Mr. Macready did on July 1st by resecting a piece of the ninth rib immediately above the former resection and making one large wound. At the time of the operation the cyst had been emptied by the patient's coughing and it was not possible to find one's way into the cyst. Consequently the patient was doomed to another two bad nights in which he was unable to lie on his back or on his side without bringing on a paroxysm of coughing and expectoration. On July 3rd, however, the cyst having become more or less filled up again, it was possible to incise it again and to insert a drainage-tube, this time with permanent good result, the cyst from now onwards draining thoroughly well. From this date the expectoration began to diminish rapidly and very soon ceased altogether; no expectoration was coughed up after July 5th. The patient began to eat well, to sleep well, to put on weight, to lose all pyrexia, and soon to look a very different man. On July 9th he was again allowed to get up. On the 17th the tube was left out of the wound in the left iliac fossa. On the 24th the wound in the left iliac fossa had healed up entirely. By August 15th great strides had been made. The thoracic wound was draining freely, and the tube was being gradually shortened. The patient had no cough and no expectoration. He ate and slept well and the temperature had been normal for the preceding four weeks. On July 23rd and the following few days there was a return of the expectoration of the golden-coloured offensive sputum which caused considerable anxiety for a time, suggesting the possibility of having to grapple with another cyst The alarm, however, proved to be unnecessary, for after a few days it ceased spontaneously and did not return. It was probably due to some temporary interference with drainage. On Sept. 11th the tubes were left out of the thoracic wound which was still discharging freely. The patient was doing well in every respect. On the 30th all discharge had ceased. The thoracic wound had quite healed. The patient had gained two stones in weight during the previous three months. He looked and felt quite well, ate well, slept well, had no cough or expectoration, could run upstairs without getting short of breath, and had no pain. The pulse, respiration, and temperature were normal. He was well marked with scars, of which he had five—(1) the scar of the laparotomy wound of May 30th, 1899, which lay between; (2) the old scar of 1888 on the left: and (3) the old scar of 1889 on the right; there were also (4) a scar in the left iliac fossa and (5) a scar at the seat of the thoracic wound. The only abnormal physical signs were in the right chest and consisted of impairment of the percussion note below the angle of the scapula and slightly weak breath-sounds at the right base. The heart's apex beat was in the fifth space, half an inch internal to the vertical nipple line. The patient was discharged from the hospital on Sept 30th, 1899, and has remained perfectly well and at his work up to the time of writing (Sept. 27th, 1900).

CARDIFF INFIRMARY.—At a meeting of the managing committee of the Cardiff Infirmary held on Oct 10th it was stated that the overdraft due to the bank had now reached £3600.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Etiology of Rheumatic Fever.—A Case of Pulmonary Valvulitis.—Sarcoma of the Lung and Supra-renal Body.

A MEETING of this society was held on Oct. 16th, Mr. WATSON CHEYNE, the President, being in the chair.

Dr. F. J. POYNTON and Dr. ALEXANDER PAINE made a communication on the Etiology of Rheumatic Fever which was an extension of their paper of the same title which was published in THE LANCET of Sept. 22nd and 29th, 1900. The present communication consisted of three parts. The first gave an outline of the experimental results obtained in rabbits with a diplococcus isolated from eight cases of rheumatic fever up to the date of the completion of the original paper in June. To these results were added some new facts ascertained since that date, and three more cases of rheumatic fever in which they had found the organism. The second part consisted of a demonstration by a series of lantern slides showing the identity of the lesions of rheumatic fever in human beings with those produced by the diplococcus in rabbits. The third part consisted of a series of microscopic specimens illustrating the morbid changes that were produced by the organism in man and in rabbits. Sketches and cultures were also shown in illustration of the paper, as was one macroscopic preparation. Dr. Poynton and Dr. Paine laid stress upon the fact that the cases of rheumatic fever chosen as the clinical basis of the original paper were characteristic ones and none of them doubtful. They briefly recapitulated the experimental results which had been obtained up to June last and described in more detail the newer facts. In one case they had isolated the organism from the throat in a case of rheumatic angina. The diplococci had been grown in pure culture in a medium of milk and bouillon rendered slightly acid with lactic acid and then transferred to blood agar. Injected by Mr. H. G. Plimmer, pathologist to St. Mary's Hospital, intravenously into a rabbit they rapidly produced death from acute valvulitis. The organisms were then isolated from the blood and cerebro-spinal fluid and cultivated as before. Injected into a young rabbit they produced polyarthritis and endocarditis. The joint effusion was considerable, but eventually disappeared entirely and the animal made a complete recovery. Since June they had detected the diplococci in three more cases of rheumatic fever, making 11 altogether, and had obtained them from the bladder after death from rheumatic pericarditis. They had also isolated them from the urine during an acute attack of pericarditis. The diplococci isolated from the urine were grown on blood agar and injected intravenously into a rabbit. Acute pericarditis, aortic and mitral valvulitis, pyrexia, wasting, and arthritis followed and resulted in death upon the twentieth day. There was no suppuration in any of the viscera. They also detailed an experimental result in which for some days definite involuntary clonic movements were noted. The movements had the characters of a chorea and in addition the animal was very nervous. With the chorea there was valvulitis. The microscopic investigation of the tissues had not yet been completed. One detail which they had recently ascertained was, they believed, of great importance. In the pericardial exudation of a rabbit that had suffered from pericarditis they had found in addition to the diplococcus, which was present in scanty numbers, some large solitary cocci. These they had already noticed as occurring when the diplococcus was grown upon unsuitable media, and they had also seen them in the human tissues. They were, they believed, an altered condition of the organism, dependent either upon loss of virulence or alteration in the chemistry of the tissues in which they were located, or upon both factors They appeared to be an evidence of subsidence of the lesion. The converse of this condition—namely, the occurrence of very numerous and small diplococci—were found in some cases of malignant endocarditis, and this they thought pointed to a local increase in virulence of the diplococci. The latent energy and vitality of the solitary cocci were possibly important from the view of rheumatic relapses. In conclusion, they felt sure that rheumatic fever was a disease to which there was great local resistance, hence the fugitive character of the arthritis, pericarditis, chorea, and other lesions usually met with in the disease. In several of these lesions they had seen the diplococci taken up by connective tissue and endothelial cells in great numbers.—Mr. EDGAR M. CROOKSHANK congratulated Dr Poynton and Dr. Paine on their researches and the beauty of their preparations. Various micrococci and streptococci had at different times been associated with various diseases of the internal organs. Some years ago he had brought forward a long list of diseases in which streptococci had been described as a causal agent. He believed they were the consequence, not the cause, of the several diseases. But the evidence adduced in this inquiry was of a totally different character. The chief interest of these researches centred around the inoculation experiments. He remarked in reference to one of the photo-micrographs which had been shown that the organism had some resemblance superficially to that of rabbit septicæmia. It was only a superficial resemblance, but he would like to be quite sure that this disease had been excluded by subsequent inoculation.—Dr. FREDERICK BATTEN remarked on the effect that the poisons seemed to have on the nervous system. One of the rabbits experimented on had had paralysis of the hind legs. This might, he thought, be of a choreic nature because he had known dogs suffering from chorea to have paralysis in the hind legs and choreiform movements in their forelegs.—The PRESIDENT asked how Dr. Poynton and Dr. Paine has isolated the organism from the throat. Bacteria had been found in rheumatoid arthritis and he would like to know whether they thought the organism which they had discovered was related in any way to the one in that disease.—Mr. S G SHATTOCK asked how Dr. Poynton and Dr. Paine had differentiated the organism they had found from Fraenkel's pneumococcus.—Dr. PAINE, in reply, said that the kidney had been found to be affected in most of their animals. As regards the procuring of the organism from the throat every care had been taken and great precautions observed to avoid contamination in the inoculations. The results obtained were very constant. As to the isolation of the organism from the throat, this source was

Mucus was taken from

l directly into the medium

terwards blood-agar was inoculated.—Dr. POYNTON, in reply, said that the pneumonia and pleurisy which occurred in rheumatic fever were no doubt actually of a rheumatic nature. As regards the possibility of rabbit septicæmia the dose administered had been considerable and the animals would have died within a few hours had it been that virus, whereas they lived many days.

Dr. T. CHURTON (Leeds) read the notes and exhibited specimens taken from a case of Pulmonary Valvulitis The patient was a child, aged 11 years; she was quite well until five years of age when she had her first attack of rheumatic fever. At the age of eight years she had hæmoptysis and developed pulmonary tuberculosis. The following year she had another attack of rheumatic fever complicated by acute pneumonia. During her last illness there was a loud rushing bruit heard along the second left intercostal space and the case was diagnosed to be one of pulmonary stenosis. After death there was found to be a narrowing of the pulmonary orifice around which was a fringe of vegetations. The ductus arteriosus, septum ventriculi, and foramen ovale were all closed. Dr. Churton suggested, in view of the researches which Dr. Poynton and Dr. Paine had brought before the society, that the pneumonia which complicated the rheumatic fever might have been of rheumatic nature.

Dr. O K. WILLIAMSON showed specimens of Sarcoma of the Lung and Suprarenal Capsule, remarking that there was no pigmentation of the skin during life.—Dr. A. F. VOELCKER remarked that it was very rare to find pigmentation of the skin associated with disease of the suprarenal capsules.

CLINICAL SOCIETY OF LONDON.

Presidential Address.—Acute Actinomycosis.—Gastrotomy for Hæmatemesis.

THE first meeting of the present session of this society was held on Oct. 12th, Sir RICHARD DOUGLAS POWELL, Bart., who had been elected President for the second time, being in the chair.

The PRESIDENT delivered his opening address, and after

sc

tl of the Transactions of the Clinical Society of London. He remarked that on looking back over the past three decades the work of the society had completely justified its existence and afforded encouragement for its future development. In his inaugural address in 1868 Sir Thomas Watson laid it down as the great object of the society to attain to "more exact *knowledge, and therefore more direct and intelligent* purpose and more successful aim, in what is really the end and object of all our labours—the application of remedies for the cure and relief of disease." While rational therapeutics must follow in the wake of advancement in pathology and etiology it was remarkable how often the employment of a remedy had preceded an adequate knowledge of the malady for which it was used. In illustration of this the President quoted the use of mercury, which had been administered for syphilis for nearly four centuries, of digitalis, which had been in use for over a century, of cinchona, of arsenic, and of salicin which had been more recently given in cases of rheumatic fever. Sir William Jenner only 25 years ago spoke at a meeting of that society of "the contagious quality of acute specific diseases as something which was given off from some part of the sick which can, when properly applied, excite the same disease in another person, and which can excite no other disease" During the past 15 years that "something" of which Sir William Jenner spoke had been rendered clear in many of the specific diseases. The triumphs of surgery that had ensued upon an increasingly exact recognition of the organism which was responsible for suppuration were such that they were scarcely able to realise the "dark ages" that ended less than a century ago. The President then referred to the prophylactic measures that were now being adopted and hoped that during the session there would be some contribution on the results of preventive inoculation against enteric fever. The question of artificial immunity was becoming one of increasing importance to the military, naval, and civil servic

sanitation rendered them incre

which must for long remain

tropical regions of our vast empire. He then referred to a series of cases in which phlebitis and secondary embolism had occu could in no way be

accountec he operation or in the

sanitary Perhaps the cases were explained by an unpreparedness of the patient for surgical injury which caused a morbid reaction to local damage During the life-time of the Clinical Society of London the use of electricity for diagnostic purposes had made great progress, and in the last few years radiography had been used with excellent results. One of the most valuable contributions to the science of medicine, and one to which the society had largely contributed, was the description and thorough elucidation of the disease now known as "myxœdema." Described first by Sir William Gull, it was afterwards thoroughly investigated and reported on in a special volume of the Transactions of the Clinical Society of London by a committee presided over by Dr. W. M Ord The subsequent treatment by thyroid extract gave an impetus to the investigation of the influence of internal secretions upon mental and physical health and upon formative symmetry, and the most recent and suggestive outcome in this category was that of the relationship between disease of the pituitary body and that want of control of growth which characterises acromegalous disease. The President concluded by remarking that a glance through the records of work done by the society gave encouragement and suggestions for work in the present and future.

Sir DYCE DUCKWORTH read notes of a case of Acute Actinomycosis occurring in a youth aged 19 years, who was admitted to St Bartholomew's Hospital on Sept. 28th 1899, complaining of pain and swelling on the lower part of the chest. There was a history of gastric pain after food some months previously, but this had passed off. On admission the temperature was 99° F. and the pulse was 100. The respiratory movements were deficient in the left lower lateral region of the chest, where a bulging gradually became apparent, which was more prominent in the left hypochondriac region. There was dulness on the left side in the axillary line below the sixth rib, where the breath sounds were absent. There was also dulness for four inches behind on the left side with friction crepitus. The bulging was partly thoracic and partly abdominal and appeared to involve the left lobe of the liver. The tumour was very tender on palpation. It moved to some extent with the diaphragm. On Oct. 25th the temperature rose to 102·2° and on the 26th to 102·8°. Abscess of the left lobe of the liver was suspected and attempts were made to locate the abscess but without success. Sir Dyce Duckworth suggested the possibility of its being case of actinomycosis, but a diagnosis could not be made. The patient was then transferred to the care of Mr. Howard Marsh who carried out further explorations but without result. On the 25th laparotomy was performed and a swelling situated below and behind the left lobe of the liver was found but no pus was reached. The patient's condition became worse and ultimately he died. At the necropsy a softened patch was found near the cardiac end of the stomach and a probe readily passed through it into a mass of spongy actinomycotic growth in the left lobe of the liver. The growth had evidently spread indiscriminately, involving the liver, the diaphragm, the left lung, and other parts. There was a subphrenic abscess of considerable size containing pus of a yellowish-green hue with numerous dark green or black granules which proved to be masses of ray fungus. No septic organisms were present. In the absence of data enabling the diagnosis to be made during life iodide of potassium was not given Sir Dyce Duckworth questioned the probability of the infection having taken place through the gastric ulcer, since if that had been the case other infective matter must have entered also. He recalled a very similar case in the St. Bartholomew's Hospital Reports for 1895. Both of these cases showed that the form of this disease as met with in man might be attended by considerable burrowing and some suppuration internally.—Mr. Howard Marsh remarked that considerable attention had lately been directed to the subject of sub diaphragmatic abscess. This was the first case of that condition depending upon actinomycosis which had come under his notice, although there had been cases recorded where actinomycosis had started in the appendix and spread upwards to the lower surface of the diaphragm, to the lungs, and even to the pericardium. He thought that in the present case it was quite possible that the infection might have been introduced through the gastric ulcer in the stomach. It must be considered a rare condition to find actinomycosis in the subdiaphragmatic space. The present case seemed to show that the ray fungus must be a very active pyogenic organism and capable of giving rise to acute infective inflammation. There had been considerable elevation of temperature and constitutional disturbance, yet after death little or no suppuration had been found. From his knowledge of the disease it would appear to be more dangerous in man than in the lower animals. The chief clinical importance of this case lay in its obscurity. Sir Dyce Duckworth's suggestion of actinomycosis seemed probable during life, but there was no actual confirmation of it. The case under discussion seemed to show that but little good was to be derived from surgical measures in such cases.—Mr. Rickman J. Godlee could not agree with the previous speaker that surgical measures were not available in actinomycosis, for when it occurred in the cæcum, the abdominal wall, the face, or the neck the diseased tissues could be scraped and cases recovered. He had come across 15 cases of the disease. There were two points of interest in Sir Dyce Duckworth's case. The first was the involvement of the pericardium, which was probably very rare though not surprising, because the disease spread indifferently among all tissues. The second point was the acuteness or rapidity of the process. Mr. Godlee referred to a case resembling it in this respect. In that instance the disease began in May and the patient died in December. The earliest symptoms pointed to pleurisy which was followed by empyema, the pus being evacuated. Soon afterwards an abscess appeared in the forearm and finally another over the front of the sternum. In the latter position there was dulness and after death a tumour was found there in which the ray fungus was discovered. The treatment by iodide of potassium in some cases was very disappointing, though in others it was very successful. A few months ago he saw a case of empyema which resisted treatment. Subsequently a tumour appeared in the abdomen which was incised. It contained but very little pus but the hæmorrhage was very free, and these features were always suggestive of actinomycosis. The abdominal lesion was scraped and large doses of iodide were given, and the patient made a good recovery.—Mr. W. G. Spencer remarked that in some cases of intestinal actinomycosis a grain of corn had been found which had been the carrier of the infection, and he asked if search had been made in the case under discussion. He had recently seen a case in consultation with Dr. Blake Maurice of Marlborough which resembled one published by Professor Illick in his treatise and he was thus able to identify the condition. In this case also the process has been very rapid. It started as a swelling and soon resulted in a large brawny induration down the neck. On examining the throat under chloroform the mass was found to protrude into the pharynx. Several sinuses with ragged bluish edges formed in the neck, but they contained only a small amount of pus and a large amount of spongy material giving rise to extreme hæmorrhage. These were the features which belonged to the sinuses of actinomycosis. In two months the patient became very much worse. The sinuses were scraped and iodide of potassium was given but no improvement took place until a month later when 40 grains of iodide were given three times a day. Then the constitutional symptoms improved and the sinuses rapidly disappeared, and the patient was quite well at the present time though there were many scars in his neck. He believed that the disease was much more common among cattle than was generally supposed, and when they presented swellings on the jaw the veterinary surgeon was called in who treated them with iodide of potassium, and the animals were then fattened up and sold for meat. He thought that it was an important question whether in the public interest such procedures ought to be allowed. In Germany such animals were slaughtered and not allowed to be used for food and he thought that that was the proper course.—The President asked what doses of the iodide of potassium had been given in Mr. Godlee's case. It was no use giving small doses. He remembered a case which he had seen with Mr. Godlee in which that remedy was very freely given internally and applied locally without success.—Mr. Godlee replied that the patient, a girl, aged 19 years, had taken one-drachm doses thrice daily.—Mr. Marsh, in reply, said that his remarks as to the inapplicability of surgical treatment referred, of course, only to deep-seated lesions. In making a diagnosis of these cases it was important to bear in mind that the clubs of the fungus were not always found in man and the diagnosis had to be made by the presence of the mycelium alone.—Sir Dyce Duckworth, in reply, spoke of the necessity for care in avoiding confusion of these growths with syphilomata—a mistake which was liable frequently to occur in view of their curability by iodide of potassium.

Mr. C. W. Mansell Moullin read the notes of three cases in which he had performed Gastrotomy for Hæmatemesis. They will be found in full at page 1125 of our present issue.—The discussion of these cases was postponed for some future occasion, when it was suggested that a debate on the surgical treatment of hæmatemesis should take place.

A vote of thanks to the President for his address terminated the meeting.

BRITISH GYNÆCOLOGICAL SOCIETY.

Treatment in Gynæcological Cases.—Exhibition of Specimens.

A meeting of this society was held on Oct. 11th, Dr. W. J. Smyly, the President, being in the chair.

Dr. Heywood Smith read a paper on Treatment in Gynæcological Cases. He considered that so much predominance had been given to the surgical aspect of gynæcology during recent years that it might not be unprofitable to discuss it from the medical standpoint. First of all he defined his use of the word "treatment" in its technical significance, illustrating it by the remark frequently made, "I did not have an operation but only treatment." He pointed out several difficulties in the classification as to medical and surgical, general and local, and of operations and treatment, whether major or minor. As to operations he said that with their present asepsis some major operations in skilled hands might be less risky to the patient than some minor operations conducted, it might be, with less scrupulous care. So with regard to time it was often a matter of importance to patients to run a little extra risk to have the prospect of cure in a few weeks by some operation rather than to lie up for months while undergoing some prolonged treatment. An organ, as the mamma, which had not been called into active use was, he contended, more often attacked by serious disease than one that had passed through a galactiferous activity, while in the case of the uterus it was the organ that had been impregnated that was more amenable to disease than one which had not passed through that condition. Dr. Heywood Smith then went briefly through the various maladies in which patience and "treatment" might often bring about a desirable result without subjecting the patient to the (to her) dread of an operation, such as misplacements of the uterus in their earlier stages, chronic inflammations, whether of the endometrium or the cervix, fibrous tumours of the uterus at their commencement, and ovaritis and salpingitis where not gonorrhœal or so chronic as to tend to chronic invalidism. He combated the error that many practitioners fell into of calling granular inflammation of the lips of the uterus "ulceration" of that organ, and with regard to the origin of fibrous tumours he suggested that in many cases they were due to the suppression of sexual impressions, and as to these tumours and inflammatory affections of the appendages, taking into consideration the sexual elements, he prescribed physiological rest. In all these he gave an outline of what the treatment should be before they severally developed into the stage that necessitated surgical interference In considering cancer—that opprobrium of medicine, inasmuch as all operations for its extirpation were often not necessarily final—as invading both the uterus and mamma, he thought that some method of treatment might be found which would arrest the disease in its earliest stages. He pointed out the necessity of examining every woman complaining of intermenstrual bleeding, contending that the patient's friends and her medical attendant were not infrequently the cause of fatal delay by making light of such premonitory symptoms. With regard to the mamma he contended that morbid conditions of that organ were often secondary to affections of the uterus, and when these latter were cured the mammary trouble subsided. He trusted that the consideration of this subject as tending to prevent the pendulum of practice swinging too much to the surgical side might not prove to have been misspent.

Mr. SKENE KEITH remarked that the society rather tended to ignore the medical side of gynæcology and the paper which they had heard was a welcome change. And yet it was noticeable that in the paper there was evidence of a continual hankering after surgical interference except in the direction [illegible]d to be resorted to early—namely, [illegible] disease. In the case of cancer, [illegible] of the uterus, no "treatment" of any kind was permissible in the early stages except removal. Dr. Heywood Smith had mentioned a case in which sarcoma of the ovary was followed by a tumour in the breast, but there was no evidence in the history of the case to show that the breast tumour was sarcomatous. It was a noteworthy point that after operations for sarcoma the patient often remained quite well for nine months and yet succumbed with a return of the disease within 13 months.

Dr O. H. F. ROUTH compared the various types of gynæcologists to the political types of extreme conservative, extreme radical, and moderate, and said that this personal factor had an influence on the question of operation. There were other points to be considered, such as the wishes and the circumstances of the patient. He related three cases to illustrate the close sympathy which existed between the uterus and the breasts.

Mr. F. BOWREMAN JESSETT commented on Dr. Heywood Smith's statement that cancer of the breast was more common in single women than in married women and said that he would like to know the source of Dr. Heywood Smith's information, for experience at the Cancer Hospital, Brompton, showed the reverse to be the case He agreed with Dr. Heywood Smith's remarks about cystic breasts. He had found no treatment of any use for this condition and his practice was to send the patient away to the seaside for some months, and if then there was no improvement he advised the removal of the breast, because these cysts were often the precursors of cancer He had tried oöphorectomy with the administration of thyroid in four or five cases of inoperable mammary cancer, but in none was there any improvement.

Dr. INGLIS PARSONS said that endometritis was often due to prolapse of the uterus, and the erosion and discharge frequently cleared up if the uterus could be kept in position with a pessary. For local application in these cases he had tried pure carbolic, iodised phenol, and liniment of iodine, and had found the last to give the best results For menorrhagia sometimes no organic cause could be found, and curetting showed no thickening of the endometrium. Some operators under these circumstances had resorted to hysterectomy, but he had obtained very good results from the constant current.

Dr. HERBERT SNOW protested against any "treatment" for tumours in the breast in women after middle age even in the case of cysts, for in his experience such cysts always developed into cancer sooner or later. He agreed with Mr. Jessett that cancer of the breast occurred more often in married women than in single women.

Dr. HENRY JELLETT (Dublin) drew attention to the statement in the paper that the prophylaxis of tuberculosis of the Fallopian tubes was fresh air, and asked if this was so how did Dr. Heywood Smith diagnose the condition? Did he first open the abdomen to make his diagnosis and then use the fresh air cure? Dr. Heywood Smith had also stated that tuberculosis of the tubes was very rare; yet the French school, which attributed the majority of suppurative affections of the adnexa to the gonococcus, admitted that one out of every four cases of pyosalpinx was due to tubercle. The experience at the Rotunda Hospital, Dublin, confirmed the view of the frequency of tuberculous salpingitis.

Dr. H. MACNAUGHTON-JONES agreed with previous speakers that such a paper as this was of peculiar value. From the chair he had repeatedly emphasised the importance of having more medical papers at their meetings. If the purpose of Dr. Heywood Smith's paper was to put a sort of curb on gynæcological operations it was not possible to discuss it exhaustively and in detail, but they must be content with general principles They must ask, "What is gynæcology doing now?" and the answer would be that it was advancing in proportion as it was based on an accurate pathology; for methods of treatment that were not so based were being discarded, whilst those that had a pathological basis were increasingly successful. True conservatism in gynæcology consisted, not in tampering with disease, but in proceeding at once with radical measures in every case in which there was no definite prospect of cure by milder means.

After some remarks by Dr. FREDERICK EDGE (Wolverhampton) Dr. HEYWOOD SMITH briefly replied.

Mr. F. BOWREMAN JESSETT showed: (1) A large Fibromyoma of the Broad Ligament removed by Hysterectomy; (2) a Fibro cystic Tumour of the Uterus removed by Hysterectomy; and (3) a large Hydronephrosis mistaken for an Ovarian or Hydatid Cyst.

Dr. HERBERT SNOW showed a specimen of Uterine Fibromyoma removed by Hysterectomy.

Dr. FREDERICK EDGE showed a Myoma of the Broad Ligament removed by Enucleation, the uterus being left behind

In the discussion on these specimens the PRESIDENT, Dr. F. A. PURCELL, and Dr. SEPTIMUS SUNDERLAND took part

---

FORFARSHIRE MEDICAL ASSOCIATION.—A meeting of this society was held on Oct. 5th in the University College, Dundee, Mr. C. S Young, Vice-President, being in the chair —The Chairman referred to the loss the association had sustained in the death of the President, Dr. Aymer of Bervie—a man struck down in the prime of life, who had endeared himself to all his patients and would be mourned by all the country side. The Chairman moved:—

[illegible] of the Forfarshire Medical Association desires to [illegible]

Dr. R C. Buist seconded this and drew attention to the fact that though not resident in the district of the association he had become a member and was rarely absent from their annual meetings.—The motion was agreed to.—Dr. A Don then showed a specimen of Epithelioma of the Penis and of Sarcoma of the Tibia. This latter was removed by amputation through the lower third of the [illegible] from a patient aged 30 years. A section of the [illegible] shown under the microscope.—Dr. J. Gray showed a Cast of Hydrocephalus in a boy, aged six and a half years, and also a specimen of Malignant Stricture of the Sigmoid which he had removed by operation. A [illegible] section of the tumour was shown, being that of [illegible] lumen of the [illegible] of the sigmoid [illegible] explained

Bedrest the object of which was to keep the patient warm while sitting up. This was effected by means of hot pans passed into the framework. He stated that it was the invention of a lady and read her description to the meeting.—Dr. Buist gave notes of four cases of Abdominal Tumours on which he had operated. In all of these more than one lesion existed. In one case he removed a multilocular ovarian cyst and a second tumour, sausage-shaped, which proved to be a dilated appendix. The patient did well. From a second case he removed gall-stones from a distended [illegible] ovary, and also sutured the crural canal [illegible] had protruded. In a third case he removed the uterus for retroversion and a mobile tumour of the size of a child's head, but this case was still under treatment.—Dr. G. Halley spoke and Dr. Buist replied.—Professor J. A. C. Kynoch gave notes of a case of Henoch's Purpura and made some remarks on this form of purpura. His case was that of a girl, aged eight years, in whom there was first a stage of lethargy followed in 12 or 24 hours by severe abdominal pain and purpuric spots, which then subsided and the patient remained well till another attack. This child had six attacks in two months.—Dr. C. McVicar said he had attended two similar cases, in one of which the heart was affected, and he wished to know if there was any such affection in Professor Kynoch's case, and thought the condition of the heart might explain the symptoms.—Professor Kynoch replied.

Folkestone Medical Society.—A meeting of this society was held on Oct. 5th at the house of Mr. W. F. Chambers.—Dr. Percy Lewis read a paper on "Local Hospitals with Special Reference to Our Own." [illegible] hospitals were that cases of sudden [illegible] treated at once and that a certain nu[illegible] in the locality could be kept trained [illegible] ready to deal with such emergencies. They also served as a valuable means of increasing the knowledge of the local profession who should be encouraged to attend operations and see [illegible] Opportunities should also be afforded [illegible] who wished to conduct any special [illegible] He advocated making temporary appointments on the staff if any local medical man happened to be specially qualified in [illegible]thalmic surgery. The staff should [illegible]rit and not by favouritism and th[illegible] helped in every way by the local profession by sending in interesting cases with the history fully detailed. Financial loss generally resulted by being on the staff, owing to the time spent in unremunerative work. To be on the staff of a hospital it was advisable that a man should work harmoniously with his colleagues, should not be injudicious in his conduct, lazy, or apt to use the appointment solely as a means of advertisement. Dr. Lewis considered that a local hospital should always have a nursing institute attached, as it would insure only well-known reliable nurses being engaged.—A most interesting discussion took place, in which the following took part: Dr. T. Eastes, Dr. W. J. Tyson, Dr. P. V. Dodd, Mr. W. F. Chambers Dr. C Latter, Mr. Thornton Gilbert, Dr. C. E. Perry, Mr. W. P Barrett, Mr. H. A. Powell, Mr. Randall Davis, Mr. A. J. Gore, Dr. J. Hackney, and Dr. A. E. Larking.

West Kent Medico-Chirurgical Society.—The first meeting of the forty-fifth session of this society was held on Oct 5th at the Royal Kent Dispensary, Greenwich. The chair was taken at first by the outgoing President, Mr. C. J. Parke, and afterwards by the newly-elected President, Dr. Septimus Sunderland.—The treasurer's accounts and the council's annual report having been adopted and three ordinary members and one honorary member having been elected, a ballot was taken for the election of officers and council for the session 1900-1 The following were elected:—President: Dr. Septimus Sunderland. Vice-Presidents: Dr. George Herschell and Dr. Thomas C Meggison. Council: Mr. Charles J. Heath, Mr. Arthur E Joscelyne, Dr John Matheson, Mr. William Henry Payne, Dr Robert E. Scholefield, Mr. G. Chisholm Williams, and Dr. H. Bowen Williams. Treasurer: Mr. John P. Purvis. Secretary: Dr. John P. Henry Librarian: Dr. F. S Toogood.—Dr. Scholefield showed cases of Tabes Dorsalis and of [illegible] and two cases of Lupus, one of [illegible]ured and the other much benefited by treatment by the Roentgen rays.—Dr. Toogood showed a case of Excision of the Knee-joint and a case of Cirrhosis of the Liver with Extreme Ascites which had been very much improved by Morison's operation.—Mr. Chisholm Williams showed cases of Hallux Valgus with Casts, Skiagraphs, and Specimens.—A discussion followed and the meeting adjourned.

Reading Pathological Society.—The fifty-ninth annual meeting of this society was held at the Royal Berkshire Hospital on Oct. 11th.—Mr. J. Bland-Sutton gave an oration on Some Points in the Diagnosis and Treatment of Uterine Fibroids. The orator stated that uterine fibroids were never recognised clinically before the age of 25 years, though they did occur between 20 and 25 years. Uterine fibroids had to be diagnosed from almost every tumour occurring in the abdomen. He dwelt on the difficulty in diagnosis and said that mistakes [illegible]tant and dangerous when the diagnosis [illegible] made in mistake f[illegible] these cases operations were not [illegible]d gone about in great misery suffering from sarcoma, dermoid cysts, hydatid cysts, and [illegible]ed correctly, would have been [illegible]nce of a venous hum on auscultation and metrorrhagia were strong evidence of fibroids. Wandering spleens had a remarkable tendency to get into the pelvis and to cause difficulty in diagnosis. Tumours more or less incorporated with the uterus and accompanied by menorrhagia and metrorrhagia were particularly difficult to diagnose, such as enlarged tubes, retroversion of the gravid uterus, &c.—A hearty vote of thanks was accorded to Mr. Bland-Sutton for his oration and the members and visitors to the number of 40 afterwards dined together at the Great Western Hotel.

Pathological Society of Manchester.—The annual meeting of this society [illegible] Owens College on Oct. 10th, the President, Mr. W. Thorburn, being in the chair.—The reports of the treasurer and committee having been adopted officers for the ensuing session were elected as follows:—President: Dr. A. T. Wilkinson. Vice-Presidents: Dr. A. Brown and Mr. J. Collier. Treasurer: Dr. T. A Helme. Secretary: Dr. T. N. Kelynack. Committee: Mr. G. O. C[illegible] Dr. J. G. Clegg, Dr. F. J. H. Coutts, [illegible] Dr. W. E. Fothergill, Dr. F. C. [illegible] E. Platt, and Mr. J. H. Ray. Auditors: Dr. A. H. Hopkinson and Dr. M. P. Ledward.—The meeting was mainly devoted to the exhi[illegible] Delépine gave a [illegible]s of Plague.[illegible]tions illustrat[illegible]n.—Dr. C. H. Melland showed Preparations of Blood presenting Malarial Parasites.—Dr. Moore showed preparations showing Various Lesions of the Liver.—A lantern demonstration of the Pathology and Morbid Histology of General Paralysis of the Insane, by Dr. David Orr and Dr. T. P. Cowen, was postponed until the next meeting of the society.

Hospital Sunday in Plymouth.—Oct 21st is to be observed in Plymouth as Hospital Sunday. The amount received in 1899, as a result of 258 collections, was £809, and from 72 children's collections £67.

Kashmir Mission Hospital and State Leper Hospital.—From the report of the Kashmir Mission Hospital for the year 1899 it is evident that the medical officers, Mr. Arthur Neve, Dr. Ernest F. Neve, and two native house surgeons, have been very busy. The "surgical summary" is as follows: operations, 4148; chloroform administrations, 871; new out-patients, 19,161; total visits, 41,629; medical in-patients, 108 (with three deaths); and surgical in-patients, 1220 (with eight deaths). As usual, the proportion of surgical cases requiring operation was very high: 856 operations were performed for entropion alone and 240 for pterygium. 93 cataracts were extracted, of which 86 were successful. There were 250 operations for bone disease, of which 65 were for necrosis of the tibia. 304 tumours were excised. There were 29 cases of epithelioma of the thigh and 15 of the abdominal wall due to burns and subsequent irritation from the heat of the portable brazier (*kangri*) which the people carry under their clothes in the winter. There were 24 cases of sarcoma. At the beginning of 1899 there were 65 patients in the State Leper Hospital; in the course of the year there were 132 admissions and four deaths. The Maharajah and the State Council made a grant of Rs.5996 to the Leper Hospital.

Reviews and Notices of Books.

The Structure and Functions of Bacteria. By ALFRED FISCHER, Professor of Botany at the University of Leipsic. Translated into English by A. COPPEN JONES. Oxford Clarendon Press. 1900. Pp. 198.

ONE of the most noteworthy features of this excellent work and translation is, perhaps, the suggestions that are made for a new classification of bacteria. We fear that the change in nomenclature would be so inconvenient, the present names being so deeply fixed in our minds, that the suggestions, admirable and scientific as they are, will be very slowly realised, if realised at all. Professor Fischer suggests that the classification of bacteria might be arranged into two orders: (1) haplobacterinæ and (2) trichobacterinæ, divided and subdivided into families. Under the first order would come the coccaceæ with the sub-families of allococcaceæ (including most cocci and, of course, the pathological staphylococci) and the homococcaceæ, which would include the streptococcus. The second family of the order of haplobacterinæ would be the bacillaceæ, which embraces as sub-families the bacilleæ (including the bacillus typhi and [illegible]

pernicious types. [illegible] word

but all othe[illegible]
biological divisions,

As to the origin of these first forms of life the author says that it seems probable that the first organisms did really arise from inorganic matter by spontaneous generation and that, as the evolutionary theory assumes, all other living beings have been gradually evolved from them in continued series. The doctrine of evolution once admitted on these lines it must also be conceded that the evolution of new species is still going on, new organisms arising continually by spontaneous generation. This reflection is enough to stagger the bacteriological student in his endeavour to capture all known species for culture and differentiation.

So far we have referred only to the subject-matter of the first five chapters of Professor Fischer's undoubtedly classical work. Leaving the considerations of morphology, taxinomy, and the distribution and origin of bacteria, we come to some most interesting chapters (Chapters VI. to IX.) on the chemical composition of bacteria, the food-stuffs of bacteria, the respiration of bacteria, the influence on bacteria of physical agents, and, lastly, the action of chemicals upon bacteria and the nature of such action. Then follows the story of bacteria in their relation to the circulation of nitrogen and carbon dioxide in nature. We doubt if the [illegible] XVIII.) refer to bacteria in relation to disease, and the interest of the reader is still maintained by the lucid presentation of the subject. Professor Fischer is astute enough to observe in his opening observations on the pathogenic species of bacteria that the descriptions will be confined to the general biological characters of the organism, purely medical questions being left to the specialist who alone is entitled to discuss them. As one of our highest authorities on botanical questions Professor Fischer's account of the pathogenic species remains a masterly piece of writing in spite of this disclaimer.

It is interesting to learn that Professor Fischer discounts somewhat the researches of Buchner on alcoholic fermentation without yeast cells—a series of researches which threatened to overthrow all our notions of fermentation. Fischer says that so far the statement is too incomplete to upset existing theories, and he adds that solid proofs of the existence and activity of the zymase are wanting. He considers that further researches are necessary to show whether a genuine enzyme is the cause of the fermentation, or whether it is not rather due to the pressure extract itself "which is, indeed, nothing more or less than a concentrated infusion of protoplasm squeezed out of the cells and preserved, as it were, in its own juice."

It may confidently be said that Professor Fischer's book is of first importance and that there is no work in the English language which deals so ably with the present position and extent of bacteriological science. The German work has for its title "Vorlesungen über Bakterien," and the lectures were intended by the author to be an introduction to general bacteriology. The German edition is recognised as a standard work upon the subject and we are sure that the English edition will be just as favourably regarded. The work of translation is done with great ability and skill, and it is not difficult to recognise in the English rendering the clear and masterly method of exposition of the German author.

Treatise on Orthopædic Surgery. By EDWARD H. BRADFORD, M.D., Surgeon to the Children's Hospital and to the Samaritan Hospital, Assistant Professor of Orthopædic
S[illegible]
L[illegible]
p[illegible]
Illustrations. [illegible]
Tindall, and C[illegible]

ALTHOUGH this is the second edition of this work the progress of orthopædic surgery since the appearance of the first edition has necessitated such large alterations that a great part of the book has been re-written, and it may be looked upon as almost a new treatise. The scope of orthopædic surgery has never been very clearly defined and has varied gr[illegible] The authors of this work have inc[illegible] expected in such a treatise [illegible] not properly come within t[illegible]

The descriptions of [illegible]
and exact, and altho[illegible]
treated with much gr[illegible]
said that any lacks the full consideration which it deserves. The account of congenital dislocation of the hip is especially good. With regard to its etiology the authors do not favour the view that it is due to an arrest of development of the acetabulum, for they hold that the deficiency of development which is met with is no more than should result from the absence of the head of the femur from the cotyloid cavity; they do not, however, offer any more feasible explanation.

In the account of caries of the spine we are told that a retro-pharyngeal abscess resulting from cervical caries is best opened by using a partly protected bistoury through the mouth. This is directly in opposition to modern surgical teaching; for when the abscess is thus opened it is hardly possible that the abscess cavity should not become contaminated by micro-organisms from the mouth, with the result that the morbid process in the vertebræ is accelerated and that sapræmia occurs. A retro-pharyngeal abscess should be opened by an incision along the posterior border of the sterno-mastoid; in this way the contents are readily evacuated and the chance of septic infection is much lessened.

In the account of rickets the statement is made that "Hutchinson's teeth" are met with in that disease. Certainly in rickets the teeth may be, and often are, malformed, but the typical teeth described by Mr. Hutchinson are not met with in rickets. In the account of "housemaid's knee" the bursa which lies beneath the ligamentum patellæ is called the "deep prepatellar bursa"; this is surely a misnomer, for the bursa is not prepatellar in the least degree. The chapter on flat foot gives a very good account of the causation, pathology, and treatment of this condition, and many other portions of the book might be named which are deserving of high praise. The only objection that might be brought forward is that in treatment the authors are not always sufficiently definite in saying what methods they themselves consider to be the best.

The book is adequately and even profusely illustrated, but some of the plates which have been reproduced photographically show very little detail.

A Short Practice of Gynecology. By Henry Jellett, B.A., M.D Dub. London: J. & A. Churchill. With 125 Illustrations. Crown 8vo. 1900. Pp. 436. Price 7*s.* 6*d.*

This little manual is a worthy companion to the author's "Short Practice of Midwifery," a second edition of which has already appeared. Like that book, as Dr. Jellett tells us in the preface, it represents in its essentials the practice of the Rotunda Hospital, Dublin, and it has on that account an added interest. The book consists of two parts. The first 15 chapters treat of the affections of the genital organs and the remaining eight of the various gynæcological operations.

In considering amenorrhœa and menorrhagia the author adopts the division of their causes into those arising (1) in the genital system, (2) in the nervous system, and (3) in the circulatory system. This classification we can from experience commend for teaching purposes. In classifying vulvitis, as also in the case of vaginitis and endometritis, the author has endeavoured to adhere to an anatomical classification and accordingly he divides the different forms of vulvitis into (1) catarrhal, (2) exudative, and (3) phlegmonous. This division is no doubt a good one, but the word "anatomical" hardly expresses its exact character.

In describing the various forms of displacement of the uterus use is made of an artificial position of equipoise, as it were, of the uterus, which is defined as follows: "When the axes of the body and of the cervix of the uterus coincide and are vertical the uterus may be regarded as being neither in a position of version nor of flexion." Departures from the position are considered to represent the various conditions of version and flexion. This scheme should tend to obviate some of the difficulties met with by students in understanding displacement of the uterus. A good description is given of the important subject of chronic endometritis and the author assigns as its causes congestion of the uterus and bacterial invasion. The debateable question as to the conditions under which fibro-myomata of the uterus should be operated upon is not very definitely answered, and no doubt the author is wise in not attempting to lay down hard-and-fast rules upon a matter with regard to which there is so much difference of opinion. The chapter upon Malignant Growths of the Uterus, and that upon Ovarian Cysts are both good. The pathology of mucoid and dermoid cysts of the ovary is particularly clearly described. From a perusal of the section upon the Operative Treatment of Inflammatory Conditions of the Appendages we gather that the practice at the Rotunda Hospital is to employ either the abdominal or vaginal route impartially under varying circumstances.

The last eight chapters contain clear descriptions of all the most important major and minor operations of gynæcology. The book is clearly arranged and well written. It is evidently the work of one who is accustomed to teach with method, and it should prove of considerable value to the student.

A Manual of Physiology, with Practical Exercises By G. N. Stewart, M A., D.Sc., M.D. Edin., Professor of Physiology in the Western Reserve University, Cleveland, U S A. With 336 illustrations and five coloured plates Fourth edition. London: Baillière, Tindall, and Cox. 1900. Demy 8vo. Pp 894. Price 15*s.* net

The present edition of Professor Stewart's well-written treatise has undergone revision and has been augmented by the addition of about 50 pages. The alterations and interpolations in the course of the first 400 pages are but slight and scarcely more than verbal. The sphygmometer of Hill and Barnard is, however, given with a drawing, and a description, with woodcut, of Dr. R. E. Dudgeon's ingenious little sphygmograph is introduced. Dr. Pawlow's experiments on gastric secretion, showing the direct influence of the nervous system on the discharge of the secretion, are described in fuller detail than in the previous editions. A section has been introduced giving the characters of the sediments in acid and alkaline urine respectively. The origin of the urea of the urine is discussed at great length and much evidence is adduced rendering it probable that it is formed in the liver by a process of oxidation of the proteids The isolation by Professor Abel of a benzoyl compound in the juice of the medullary portion of the adrenals, apparently causing the rise of pressure when that juice is injected into the vessels, is mentioned. The changes occurring in the contraction of muscle as illustrated by Rutherford and Schafer are fully described The chief additions that Professor Stewart has made are under the headings of muscle and nerve, but even here the main body of the text has been but little altered. We venture to advise Professor Stewart to abstain from materially increasing the size of the volume: it has reached the limits of one volume. His efforts should be directed to compression rather than to expansion. As it stands at present it will serve to give the student or practitioner a very sound knowledge of modern physiology.

JOURNALS.

Revue de Gynécologie et de Chirurgie Abdominale. Tome IV., No 4, July—August, 1900. Paris: Masson et Cie. —This number contains the following original articles. An Anatomical Study of the Fascia Enveloping the Hypogastric Arteries, by M Paul Petit; the Remote Results of Abdominal Hysterectomy for Cancer of the Cervix of the Uterus, by M. C. Jacobs; Pulmonary Embolism following Operation for Fibro myomata of the Uterus, especially Hysterectomy, by M. G. Michel; Medullary Anæsthesia or Sub-arachnoid Injections of Cocaine, by Professor T. Tuffier; and, lastly, an elaborate article upon the Use of Autoplastic Sutures in the Operation for the Radical Cure of Hernia and in Laparotomy, by M. L. Dartigues.

Practitioner.—All the original communications in the October number deal with plague, the individual contributors and their subjects being as follows. Mr James Cantlie writes on the Symptoms, Pathology, and Treatment of Bubonic Plague. He recommends Haffkine's fluid for inoculation as a prophylactic, and says that plague patients are infective for at least one month after the subsidence of the fever. Dr. Patrick Manson describes six cases of plague which came under observation at the Seamen's Hospital, Albert Dock, on the Thames, two in 1896 and four in 1900. Three patients died in the hospital, one was dead on arrival, and two recovered. Dr. R. Tanner Hewlett has an illustrated article on the Bacteriology, Bacteriological Diagnosis, Dissemination, Prophylaxis, and Serum-Therapy of the disease. Mr. David C. Rees writes on Plague in English Seaports, and Dr. A. K. Chalmers of Glasgow on the Preventive Aspects connected with the Occurrence of Cases of Plague. Finally, Dr. W. Collingridge describes the methods adopted for the medical inspection of vessels entering the Port of London and the precautions used for the discovery of infectious disease.

Edinburgh Medical Journal.—In the October number Dr. H. Macnaughton Jones publishes a long paper on Affections of the Female Genitalia as Causal Factors in the Etiology of Neuroses and Insanity. He mentions that he has never seen any injurious mental consequence follow a gynæcological operation in a healthy woman; he has met with only two cases of post-operative insanity, one of the patients having previously been in an asylum, and the other, an official in a private asylum, having been a typical neurasthenic for some years. Under the heading of Recent Advances in Medical Science Dr. A. Lockhart Gillespie notes some of the latest contributions to the symptomatology and treatment of plague. Dr. R. T. Williamson writes on the Clinical Forms and Pathological Anatomy of Spinal Syphilis, and Dr. S. W. Carruthers publishes an instalment of his papers on the Mechanism of Articulate Speech. Medical Education in the United Kingdom is dealt with in an Appendix of 36 pages.

Scottish Medical and Surgical Journal.—In the October number Dr. W. Leslie Mackenzie writes on the plague with special reference to its appearance in Glasgow. Dr. Th Shennan gives a *résumé* of our knowledge of diseases missible from the lower animals to man, the exa instanced being tuberculosis, diphtheria, scarlet glanders, farcy, anthrax, plague, foot-and-mouth d and rabies. Professor Thomas Annandale writes in of excision of aneurysms of the limbs, provided th tolerably circumscribed and free from complicatior considers that for important arteries a properly prepar ligature is the safest and best. Mr. C. W. Cathcart de a simple form of steriliser for surgical dressings in steam heat is applied by means of water contained outer jacket. An article on Medical Education in Sc gives copious details relative to the various education examining bodies.

New Inventions.

A NEW AMBULANCE CARRIAGE.

AN improved form of ambulance carriage, of which we give illustrations, has recently been designed and built by the St. John Ambulance Association for the Wanganui (New Zealand) Branch of the Association. In general arrangement it is a covered van fitted with a well the bottom of which is about 16 inches from the ground. At the rear of the carriage are two doors as shown in the illustration The carriage is adapted to carry two patients, one in a recumbent position on a Furley stretcher fitted with telescopic handles placed on the near side of the carriage and the other in a semi-recumbent position on a seat fixed on the off side. With a view to economise room and reduce the length of the carriage the space under the driver's seat has been thrown into the interior, and part of it gives room for the foot of the stretcher, while in the remainder a locker has been fixed in which surgical or first aid appliances can be carried. In this particular carriage a "medical companion" as approved by the Army Medical Department was placed in the locker. The carriage is built with an ash framework panelled with choice mahogany, the wheels being fitted with india-rubber tyres. It has a smart appearance, it runs lightly, and it is easy to load and to unload, the proximity of the well to the ground affording great help to the stretcher-bearers. In addition to being an excellent ambulance carriage the vehicle can be used as an omnibus and is capable of carrying five persons inside in comfort. Mr. S. Osborn, F.R.C.S., approved the design and thoroughly inspected the carriage before it was packed for shipment. A very similar carriage had previously been built by the St. John Ambulance Association for the London Hospital and it is, we are informed, giving complete satisfaction.

THE LANCET.

LONDON: SATURDAY, OCTOBER 20, 1900.

THE complete inefficiency of medical service in the highlands and islands of Scotland is a matter of urgent importance. The lot of the sick poor anywhere is a pitiable one, but it becomes doubly so when the medical man is at a great distance, when no nurse is available, and when all the conditions of domestic comfort are conspicuous by their absence. If our comments upon the situation seem to refer chiefly to the case of the medical officer responsible for the care of the sick poor in these remote regions, where moor and fen and crag and torrent and not seldom the stormy sea intervene between him and them, it must be remembered that to describe the disadvantages of his situation with a view to their rectification is to take an important step towards the better treatment of the poor. We have received and published many communications illustrating the hard life of the medical officer in the highlands and islands of Scotland, but none of them has exhausted the subject. The latest of these, which appeared in THE LANCET of Sept. 29th (p. 967), from the pen of Dr. HENRY PEARSON TAYLOR of Baefirth, Mid Yell, Shetland, in the most moderate terms indicates the impossibilities, the hardships, and the injustice of the position of the medical officer whose lot is cast in these districts The burden of Dr. TAYLOR'S complaint is that the medical officer is put into a position in which he is compelled to do terribly hard work for such a scanty pittance that he is practically giving his services. He has not only to treat those who are really paupers, but he is expected to take a benevolent view of the sickness and illness of the classes above the line of pauperism. There is a happy conceit in the interesting address of Sir JOHN WILLIAMS, which we published in THE LANCET of Oct 13th, to the effect that the Good Samaritan was undoubtedly a member of the medical profession. Perhaps the Levite and the other good people, in passing by the wounded man who fell among thieves, comforted themselves with the belief that the Good Samaritan—the doctor—was behind them and would soon come up with more help than they could render. Something of the sort seems still to be the theory in the highly religious country of Scotland, where the whole weight and care of the sick poor are thrown on a medical man who gets less than a week's holiday in a year, who is expected to be a SYME in surgery, a BEGBIE in medicine, a SIMPSON in obstetrics, and a first-class specialist all round, to have all the antiseptic armamentarium of modern operative surgery at his fingers' ends, and to be a sort of paternal providence to the community—and to consider himself remunerated by the receipt, in some places, of as much as 10*s*. 6*d*. a week. This, in a country which spends millions a year for meeting the spiritual wants of its population, is a serious state of matters and is not a little discreditable to all responsible for it, who may be considered to be the State, the Established Church, and the parish council, in the order mentioned.

Unhappily this is not a new scandal. More than half a century ago, in 1846, a voluntary association of medical men was formed, with the public-hearted Dr. ALISON as chairman, whose object was "to express sympathy with their brethren in remote country districts of Scotland in regard to their unremunerated attendance on paupers and to collect accurate information on this subject." An account of this association is given by Dr. JOHN BROWN in his paper, "Our Gideon Grays," from which the following is a quotation:—

> "Out of 325 returns 94 had received *some* remuneration for attendance and outlay. In one of these instances the remuneration consisted of 3*s* for 12 years' attendance on 70 constant and 13 occasional paupers; a fine question in decimals—What would each visit come to? But worse remains. One man attended 400 paupers for eight years and never received one farthing for his skill, his time, or his drugs. Another has the same story to tell of 350, some of them 30 miles off; he moderately calculates his direct loss from these calls on his time and his purse at £70 a year Out of 253 who report 208 state that besides attending for nothing they had to give on occasions food, wine, and clothes, and had to pay tolls, &c. 136 of the returns contain a more or less definite estimate in money value of their unrequited labours; the sum total given in by them amounts to *thirty-four thousand, four hundred and fifty-seven pounds in ten years! being at the rate of £238 for each!* They seem to have calculated the amount of medical attendance, outlay, and drugs for each pauper annually at the very moderate average of four shillings."

Some means must be found for remedying a state of matters which in most ways exactly tallies with that described by Dr. JOHN BROWN half a century ago Much assistance in the formation of a judgment as to the nature of these means will be found in a letter (published in another column) from Dr. WILLIAM BRUCE, Direct Representative on the General Medical Council for Scotland, than whom probably no living Scottish practitioner is more familiar with the wants of the medical service in the remote districts of Scotland. The hardness of the conditions is such that no adequate supply of medical help can be secured and no adequate remuneration can be given for medical service in such districts without extraneous support, and this difficulty must increase with every demand for medical service from the various parts of our ever-extending empire. There are clearly two principles in the solution of such a problem. One is the equalisation of such burdens between the State and the parish. We apply this principle in England and in Ireland. It is even in force as between the parishes of the metropolis, where the richest parishes are made to help to bear the burdens of the poorest, and all are the better for realising their mutual debts and obligations It is simply absurd that the full application which obtains in England and Ireland of so obvious a principle of political economy should still be wanting in Scotland. We venture to hope that Scotland with her rich towns and thriving industries will not much longer abstain from the honourable discharge of her duties to her own poor, whether they reside in Glasgow or in the Hebrides. If she still continues to do so we should be disposed to venture a little farther and to say that before very long these districts will be still more starved than at present and that the paupers will not be the only sufferers. Already, if we are not misinformed, the supply of medical officers in these parts is not always forthcoming. And there must also be greater security in the position of the medical officer. This has been conceded in England and Ireland and should be immediately granted in the case of Scotland. We do not mean that the local authority should have no power of removal, but that such power must be checked by the right of appeal to the central authority, otherwise, as Dr. BRUCE points out, great hardship and injustice may accrue to the medical officer. We do not deny that the character and the conduct of the medical man in these regions are even more important than in districts where there is a choice of medical men. But, on his side, the medical man practising remote from his fellows is entitled to the protection of a larger judgment than is always to be found in an intensely local body. We cannot doubt that Lord BALFOUR will take the case of the medical officers of the highlands and islands of Scotland into his consideration and secure for them a position that will maintain their efficiency and their self-respect.

WE have from time to time, even at the risk of becoming wearisome by mere iteration, adverted to the question of transport as a most important factor in war. The supply of men and materials to the front in the present war in South Africa has proved to have been a most arduous and difficult task. Even apart from interruptions of the railway lines of communication by the enemy's destructive raids delays are occasionally inevitable under the best systems of military organisation and railway management. We know what occasionally happens in this country in a time of peace in the presence of any unusual strain and can therefore form some idea of what it was in South Africa in time of war. What was the state of affairs there? The narrow gauge of the single line of railway implies diminished power of locomotives and reduced carrying capacity by the rolling stock; the steep gradients and sharp curves which are more or less present throughout the entire system, owing to the natural configuration of the country, make it necessary that the trains shall only be loaded up to the power of the engines hauling them; and the speed, which is governed by the gauge, gradients, and curves, has consequently to be *slow*. Moreover, the distances traversed were immense. Some idea may, therefore, be formed of the time required to transport and to deliver the materials necessary for the forces operating at the front. Our readers have already had the opportunity of studying for themselves the evidence of Lord ROBERTS and that of the chief of the staff, Lord KITCHENER, and others, in respect of these matters. But we would direct their attention to some remarks on hospital administration which were made by Lieutenant-Colonel RYERSON, M.D., Canadian Commissioner of the Red Cross Society in the South African War, in the course of an address delivered at the annual convention of the Canadian Medical Association at Ottawa, inasmuch as they strike us as both pertinent and interesting at the present time.

The Orange Free State (now Orange River Colony), he says, produced little towards its own support in men and horses. The main artery of communication through the remorseless and arid veldt is a narrow-gauge railway of 725 miles in length between Cape Town and Bloemfontein, where the alleged deplorable state of the sick is said to have taken place. Suddenly 100,000 soldiers and 20 000 camp followers are thrown into the country, already bare and hardly able to feed itself; add to this 25,000 horses, *mules, and oxen*; *all of them*, *men* and animals, have to be fed by this narrow-gauge railway, and all the food-supplies and munitions of war and men and animals as well as miscellaneous hospital stores have to be transported. Then an unexpected epidemic of enteric fever suddenly occurred after the troops had made their forced and rapidly-executed marches and captured Paardeberg and subsequently Bloemfontein. With this enormous increase of sick the strain on the hospital service and all connected therewith may easily be conceived. Naturally, under the circumstances, the field hospitals had to be utilised as stationary hospitals notwithstanding that they were neither equipped nor intended for such work—for which, indeed, they are not at all fitted. The field hospitals are actually with the *troops, they* accompany and take part in their movements, and have consequently to be provided with a portable equipment in order that they may move readily with the army and receive the wounded from the dressing-stations during or after an engagement with the enemy. Every field hospital should be complete in itself as regards both its *personnel* and material and it should be so constituted as to be mobile and capable of being opened and closed promptly and of temporarily providing for its inmates until they can be transferred to other hospitals along the line of communication and in the rear. Although such are the functions of a field hospital it is easy to see that contingencies may arise, such as those which have occurred in so exceptional a campaign as that in South Africa, in which a field hospital may have in cases of grave emergency to take the place of a stationary hospital for the time being. That is an additional reason why every field hospital should be a complete unit in itself and have its own transport. We have often insisted upon the importance of this provision. The field hospital should, in our opinion, be complete in every detail from start to finish of a campaign. The Royal Army Medical Corps should have their own ambulance complete, including wagons, horses, and mules. We think that the Government of the United States took a wise and absolutely necessary action during their war of rebellion in not allowing the hospital transport to be diverted to any other purpose, except in cases of emergency and under the order in writing of the general in command. There should be no requisitioning of the Army Service Corps in the field, but the necessary hospital transport should be handed over from the beginning and applied exclusively and continuously for the purpose intended. Had this been the case the evil results following Paardeberg might probably either have been averted or been materially reduced.

We quite admit that war is war. The nation has to make up its mind that in this as in all other cases it cannot eat its cake and have its cake. The more rapid

Annotations.

"Ne quid nimis."

THE REORGANISED UNIVERSITY OF LONDON.

THE administration of the new University of London is now complete It was started by the election of a Senate composed of 56 persons (including the [illegible] and the Chairman of Convocation) on Oct 12th. [illegible] of the Senate will be held [illegible]. The Senate is thus composed:- [illegible] Hon. the Earl of Kimberley Vice [illegible] oscoe, F.R.S. Chairman of Convocation: Mr. E. H. Busk. Four Crown members, including Mrs E. M. Sidgwick and Sir J. W Wolfe-Barry, F.R S. 16 members of Convocation, including Mr J. Fletcher Moulton, M.P., Sir Albert K. Rollit, Mr. Justice Cozens-Hardy, Dr. T. Barlow and Dr. J. F. Payne, Mrs. S Bryant, Sir Philip Magnus, and Professor Silvanus Thompson. The election of Convocation members was practically a large majority for the nominees of a ticket issued by Mr. Fletcher Moulton, Dr. W. J. Collins, and Mr. Willis, who secured all the seats (six) in arts and four out of the same number in science Mr. E. J. Routh, Sir [illegible] Armitage Smith, Professor Carey Foster, [illegible] Dr. S. H. Vines, and others were rejected because of their supposed approval of the changes from the old University. The Royal College of Physicians of London elected Dr W. H. Allchin and Dr. P. H. Pye Smith, F.R.S.; the Royal College of Surgeons of England, Mr. A. Pearce Gould and Mr. H G. Howse; University College, Professor G. Carey Foster, F.R.S., and Lord Reay; King's College, the Rev. the Principal, Dr. A Robertson, and Lord Lister, P.R S. The legal profession is well represented by Lord Macnaghten and Lord Davey, with other well-known names, the Corporation of London by Alderm[illegible] Dr. T. B. Crosby, J.P., and the London County Council [illegible] Dr. W. J. Collins and Mr. Sidney Webb. Sir Frederick A[illegible] epresents the City and Guilds of London Institute, and among the 16 members elected by the various faculties are: in medicine, Dr. J. Kingston Fowler, Dr. E. C. Perry, and Dr. J. Rose Bradford; whilst in science are Sir Michael Foster, M.P., and Professor W. D. Halliburton, F.R.S., Professor W. Ramsay, F.R.S., and Professor W. C. Unwin, F.R.S. Now that the *personnel* of the Senate is so well filled up and the teaching element is brought so completely in line with the institution, we would point out the largeness of the task that is before it as laid down in the statutes. The Senate is to be the supreme governing and executive body of the University and may make statutes, by-laws, regulations, and standing orders, or alter, revoke, and add to them, and in each year shall elect one of its own members to be Vice-Chancellor. There are three standing committees of the Senate to be appointed, and this will be the first duty of the new body. The Academic Council is to consist of 20 members, including the 16 elected by the various faculties, and will deal generally with the matters relating to internal students—i.e., to those who are educated in the schools of the University. The Council for external students is to be formed of 28 members, and will comprise the 16 appointed by Convocation as well as 12 others nominated by the Senate, and they will regulate and report on the standards and examinations for matriculated students who are not working in the recognised schools. The number of the members of the Board to promote the extension of university teaching is at first to be nine, but may be varied at the discretion of the Senate. It is obvious that these committees will plan most of the University work and teaching, although their functions are explicitly stated in the statutes to be merely advisory. The next duty will b[illegible] will be [illegible] by the Senate. [illegible] teachers or examiners in the faculty, or any other teachers or persons thought fit to be members of each board. These bodies are evidently the most important constituents in the reorganised University, for "the Academic Council and the Council for external students respectively, before advising the Senate upon any matter relating to courses of study, provision for teaching, or research examinations, and the appointment of examiners or the granting of degrees or certificates of proficiency, shall invite and receive reports from the boards dealing with the studies concerned." Each board may report to the Senate on these subjects or any matter referred to it by the Senate, and shall, if requested, deliberate with the Senate or any committee thereof. The faculties are composed of the teachers now approved by the Commissioners in the various schools of the University, other appointed teachers of the University, and such teachers as may be admitted into the faculty by the Senate. They have no fixed times for meeting, but can report to the Senate, and their chief object seems to be the election of representatives on the Senate as was done on Oct. 12th. They must also elect a dean in each faculty to act as chairman and to summon the meetings. Convocation has scarcely any duties or privileges, except to elect its representatives on the Senate and a Chancellor on the death or resignation of the [illegible] one.

THE NOTIFICATION OF PLAGUE.

WE are glad to have called forth by our allusion to this subject the important letters of Dr. Thomas Colvin[1] and Sir William T. Gairdner.[2] Any suggestion from Sir William Gairdner for improvements in sanitary legislation has much weight. He exposes the weak part of the Notification Acts They only require the medical man to notify when he has come to a definite opinion that the disease is one of the group [illegible] Acts. This may involve delay, longer or [illegible] to the nature of the case and partly accord[illegible] ness or the temperament of the practitioner. In the case of plague undue delay may be disastrous and in all other cases of infectious disease it is not in the public interest. Sir William Gairdner argues that the Acts should be so modified as to require the practitioner to notify not on a conviction that he is dealing with an infectious disease under the Acts but on a suspicion to that effect. Undoubtedly in many cases this would result in an earlier isolation of an infectious case, but we confess that we doubt the general expediency of sanctioning the notification of suspicions. The case of plague is exceptional and would justify every sanitary authority in special expenditure and efforts to get an early diagnosis. If the powers of such authorities do not extend so far clearly they ought to do so. It seems to us, however, that what is needed is not more notifying power but more medical attendance and, if necessary, the multiplication of medical opinions, with the provision of more isolation wards for suspected cases. The case on which Dr. Colvin and Sir William Gairdner both dwell shows that even in Glasgow as well as in the Hebrides there may be a great deficiency of medical attendance. The patient was seen by a medical man and found to have a temperature of 104° F. and to be "raving," and she was not seen again for 14 days. When Dr. Colvin visited her on Sept. 10th he had no difficulty in diagnosing plague. Obviously what is wanted in such circumstances is the multiplication of medical attendances and medical opinions—at the public expense. This has been already done in Glasgow and to this precaution doubtless, amongst others, we owe the limitation of the disease. The general notification of suspicious cases would, we fear, lead to unnecessary trouble

ICE-CREAM.

LOVERS of this "delicacy" [illegible] About the middle of August [illegible] rhœa in the district of Mer[illegible] Rochdale, and Dr. J. Henry [illegible] investigated the cases of 146 [illegible] ice-cream supplied by one ma[illegible] all commenced on Sunday, August 12th. The ages of the sufferers were from one to 51 years The severity of the illness varied from slight sickness and fainting to severe vomiting, diarrhœa, dysentery, and death in one case; in some of the cases the temperature was very high and there was extreme prostration. On Monday, August 13th, Dr Henry visited the premises of the ice-cream vendor and found that all the cream manufactured on the Friday and Saturday had been sold. Two vessels containing ice cream in process of manufacture were seen to be within a yard of the pail-closet, and the fine strainer used for straining the milk and cornflour after boiling was within about four inches of a dolly tub in which were babies' napkins soiled with diarrhœal excreta A baby in the house had been suffering from diarrhœa since the previous Friday but had not been medically attended. Dr. Henry is fully justified in his opinion that the contamination must have been introduced into the whole bulk of cream after the boiling process and before the freezing and that the cause of the contamination was probably infection from the diarrhœal motions or from the offensive closet. Considering that the ingredients of ice-cream are admirably adapted for the growth of many kinds of bacteria and that the vitality of these organisms is not destroyed by the lowest attainable [illegible] ous risk to the health of the con[illegible] prepared in close proximity to [illegible]

RADICAL MEASURES IN THE UNITED STATES TO PREVENT THE PROPAGATION OF THE UNFIT AND THE DEGENERATE.

THE [illegible] Journal in its issue of [illegible] In an editorial article to the [illegible] practical measure for prevent[illegible] types of confirmed criminality [illegible] o the relative fecundity of the [illegible] nerate or criminal progeny it says: "It requires no mathematician to discover that the shiftless, the thriftless, the indigent poor—the class which produces relatively the greatest number of criminals and paupers, if not of the mentally deficient, are increasing out of all proportion to the thrifty, the well-to do—the class which produces relatively few of the paupers and criminals. ...... Recent years have added an additional cause—viz , the lavish free treatment by hospitals, dispensaries, and lying in institutions to all who apply." The result is that the weakling, [illegible] threatens serious consequences for the future. Among the fruits of our life-saving and life-multiplying measures are the idiot, the pauper, and the congenital criminal. The article maintains that while our duty to humanity will not allow us to refuse medical aid, there remains a means under proper circumstances of preventing the multiplication of certain of these wrecks and derelicts of humanity. If the confirmed criminal, the pauper, the degenerate—who are incapable of regard for law and society and indifferent to the consequences of their own acts—must be supported by the State, then society certainly has the right to say that such at least shall not propagate their kind. "It is stated that Michigan [illegible] It is contended that a measure like this would at first affect only to a small extent the increase of the population of the degenerate and criminal sort, but it is pointed out that once this measure begins to be put into effectual operation its efficacy will increase year by year. Asexualisation will be regarded by some as a harsh measure, but nothing better has been offered by those who would seek to discourage it, and the future will (it is argued) compel us to take some step to prevent the increase of the hosts of degeneracy and criminality. Regulation of the marriage law would be ineffectual because these individuals have ceased to have respect for the law and the consequences of their own acts. It is known [illegible] already legislated on the ques[illegible] (Pennsylvania) is preparing special legislative enactments in the matter of preventing th[illegible] l and degenerate. [illegible] these measures as interesting signs of the times, and emphasises the fact that the problem of the propagation of insanity and criminality is assuming an acute phase in some of the States in the Union.

THE BRISTOL ISOLATION HOSPITAL.

THERE is no portion of the equipment of a public health department the advantages of which are more universally recognised than a well ordered hospital for the isolation of cases of infectious diseases In most of the largest municipalities of this country su[illegible] years past been doing exce[illegible] lessening, and frequently of [illegible] It has only been necessary in some towns—for example, in Liverpool, Manchester, and Bradford, where commendable foresight has been displayed by the sanitary authorities—to supplement established buildings with suitable additions as the exigencies of an increased population have rendered extension necessary. In others, again, too much reliance has been placed in the past upon the ability of boards of guardians to provide isolation accommodation for those in need of it, so that when it came to be recognised that isolation was necessary not only in the interest of the individual sick person but also of his immediate neighbours these municipalities found themselves in the position of having to erect extensive buildings that ought to have been established years ago. It is remarkable to find among these latter so progressive a city as Bristol, where for years provision for isolation has been most meagre and is even now comparatively of the scantiest. It appears that up to such a recent date as 1886 the sanitary authority of the city shared the responsibility of providing isolation accommodation with the boards of guardians, in what unequal proportions may be gathered from the statement that at one time the boards of guardians could furnish 120 beds and the city authorities only 24, and this small number even in temporary wooden buildings. Latterly, however, the corporation has undertaken the entire responsibility of caring for those who are infected and receives from the board of guardians an annual sum of £300, in return for which all pauper patients are received and treated in the city isolation hospitals. In 1892 the corporation with praiseworthy energy set about the carrying out of its responsibilities and erected at Nover's Hill a permanent administrative block and a small pavilion, and on account of a sudden outbreak of small-pox in 1893 two temporary buildings were erected with accommodation for about 22 patients In 1896 there was begun the erection of more extensive buildings upon an estate which is situated at Ham Green, some three miles from the city boundaries, 100 acres in extent, and which had been recently purchased by the corporation together with a large mansion for the sum of £8695. There is accommodation in five pavilions which have been in use for nearly 15 months for 76 patients. It will be observed, therefore, that Bristol can at the present time isolate only 100 infected persons, although the population of the city is considerably over 300,000, a number necessitating, according to the experience of competent authorities, a hospital or hospitals with at least 300 beds. The cost of the Ham Green Hospital, which, by the way, was erected by corporation workmen and without the intervention of contractors, exceeded £500 per bed, and this sum, which is certainly high, appears to have alarmed the citizens of Bristol and to have delayed the carrying out of the completion of the entire scheme by the erecting upon the very ample site a sufficient number of pavilions to meet the requirements of the city; indeed, it would seem that in some quarters the medical officer of health, Dr. D. S. Davies, has been reproved for asking to have the institution "extended" almost before it is completed, whereas in point of fact there has not been strictly any completion. It cannot be too often emphasised that the cost per bed of a hospital always decreases within certain limits as the accommodation is increased. If the number of beds at the Ham Green Hospital were doubled the cost per bed would be reduced probably to a little over £300, for the outlay upon purely administrative buildings, such as laundry, disinfecting, mortuary, and stabling is not duplicated with a duplication of pavilions. We feel sure that those who have really at heart the prosperity and the well-being of the inhabitants of Bristol will not be led away by any motives of false economy, but will give full effect to the recommendations of responsible officials—recommendations which are tendered with a full sense of the gravity of the interests involved.

MENTAL DISEASES AFFECTING THE YOUNG.

DR. F. MAGNIER, in his *Thèse de Paris*, 1900, shows that apart from idiocy and imbecility there are well-marked and characteristic mental diseases affecting the young before adult life is reached. Among these affections dementia præcox, as already shown in these columns,[1] holds a prominent place. The others include acute mental confusion, acute delirium, *folie périodique*, menstrual psychoses, and paranoia. As regards acute mental confusion it is pointed out that whereas Meynert considered the age of election of this disease to be between 20 and 30 years, several cases have been recorded of its occurrence earlier. Thus Trenel has recorded its occurrence at nine years of age in a girl, of alcoholic and neurotic parentage, consequent upon fright, and Mannheimer has recorded other cases in girls below the age of 20 years. Acute delirium with high temperature and adynamia ending fatally is recorded in two cases by Dr. Magnier, both of which occurred in females of the age of 19 years and 26 years respectively. Periodic insanity in 80 per cent. of cases begins before the age of 25 years, the depressive form occurring especially in the decade between 20 and 30 years of age. Dr. Magnier points out that an insane heredity is present in 80 per cent. of the cases, and he cites the case of a girl with periodic insanity which had its onset at the age of 14 years and was marked by agitation, insomnia, and mutism, while in a second case the disease began at the age of 12 years and was marked by suicidal impulses. Two other cases commenced at the age of 18 years and one at the age of 19 years and a month after parturition. The menstrual psychoses are characterised by agitation, loquacity (singing and talking incessantly), and hallucinations of sight and hearing. They occur during menstruation and subside soon after and recur with the menses. The clinical type is that of adolescent insanity. Though paranoia is a disease of adult life yet transitory excitement may occur in youth from time to time as a prodrome. Thus in one case symptoms of suspicion and auditory hallucination began at the age of 22 years and three years later the delusions became well marked. Another commenced at the age of 21 years. From the facts and cases recorded in Dr. Magnier's *Thèse* it thus appears that the period of youth and adolescence is liable to develop a variety of mental affections.

SANATORIA FOR PHTHISICAL PATIENTS.

IN a report on tuberculosis recently presented to the West Riding County Council, Dr. J. R. Kaye, the county medical officer, makes the suggestion that county councils should provide sanatoria for phthisical patients belonging to the middle classes and that a small fixed charge for maintenance should be made to each sanitary authority sending a patient. This, he says, need not necessarily come out of local rates if the sanitary authority were empowered to obtain it from the patient or by local effort. If 50 beds were provided, and each patient received three months' treatment, then nearly 200 persons could be treated annually. Phthisical patients who are either very poor or actually belong to the pauper class ought to be dealt with by the boards of guardians and the rich have a choice of institutions both in this country and abroad, but nothing has up to the present been done to make the advantages of sanatorium treatment available for members of the working middle class. From inquiries made at various establishments Dr. Kaye finds that the cost of maintenance of each patient receiving treatment in a sanatorium varies from 5*s*. to 6*s*. 6*d*. per day. He also quotes figures as to the cost of erection and maintenance derived from the German sanatoria at Ruppertshain, Worms, Spessart, Munich, Brunswick, Nuremberg, Marcel, Falkenstein, Grabowsee, Bremen, and Würzburg. The ordinary charges made to patients at Grabowsee, Bremen, and Ruppertshain are from 2*s*. to 3*s*. per day.

MOSQUITOES AND MALARIA.

MR. E. E. AUSTEN has published by order of the Trustees of the British Museum an interesting report upon the results of the expedition of Major Ronald Ross, I.M.S., to study the causes of malaria in West Africa. The headquarters of the expedition were at Freetown, Sierra Leone, and cases of fever were studied in neighbouring villages. Immediately after the arrival of the expedition an outbreak occurred at the village of Kissy. In the asylum where the outbreak took place mosquitoes of the genus anopheles were found upon the walls of the building, and Mr. Austen takes occasion to point out that this genus can be easily differentiated from culex by its characteristic attitude when at rest; it appears, in fact, to be standing upon its head, since the body is maintained at an angle of "at least 45°" to the surface upon which the fly is resting. A drawing of the insect in this characteristic position was published in THE LANCET of Sept. 30th, 1899, p. 912. In another place—at Wilberforce—the presence of this particular mosquito was associated with the existence of fever. The coincidence of the fly and the fever was proved by Major Ross to be a real instance of cause and effect, for at Wilberforce the bodies of the anopheletes were found to contain "malaria parasites in various stages." It is, of course, desirable for more than one reason to kill the larvæ as well as the perfect insect, and the work of the expedition was partly concerned with the discovery of the larvæ and with experiments as to the easiest way of killing them. Like other gnats the larvæ are hatched out in quite tiny puddles. As has been shown by other observers the puddles must contain some green weed to serve as food to the developing larvæ. The easiest way of killing them seems to be by pouring a little kerosene, which forms a film on the surface of the pool and thus chokes the insects which must come to the surface to breathe. Stimulated by the economic importance of these investigations upon the connexion of mosquitoes with malaria the Trustees of the British Museum have issued a short report upon the collections of these flies recently received. This work has been entrusted to the well-known dipterologist, Mr. F. V. Theobald.

---

[1] THE LANCET, Feb 10th, 1900, p. 397.

HOSPITAL ABUSE AND THE MEDICAL GUILD.

WE give elsewhere (p. 1157) the report of the Medical Guild on the question of hospital reform. The prefatory remark of the Guild only raises our appreciation of their work. They begin by saying that they are impressed with the difficulties surrounding the question. It is obvious, however, that these difficulties will only increase with the lapse of time and that no honest criticism on the subject should be resented or refused by hospital authorities. The Guild does not regard the present inquiries into the fitness of patients as adequate or satisfactory. They are of opinion that by far the greater number of those attending the out-patient department do not require any special treatment and only waste the time and energy of the hospital staff. They consider that the charges exacted from patients are wrong in principle and bad in effect. The profession generally will agree in these conclusions. Meantime the really pitiable and proper cases suffer from inadequate help owing to the presence of crowds of the unfit.

BLOOD-PRESSURE IN ITS RELATION TO ANÆSTHESIA PRODUCED BY CHLOROFORM OR ETHER.

IN the August number of the *Archives Générales de Médecine* Professor Simon Duplay and Dr. Louis Hallion have published a long article on the changes produced in the blood-pressure during anæsthesia from inhalation of chloroform or ether. The object of the investigations which they made on dogs anæsthetised with these substances was to study the respiration and pulse considered in relation to the blood-pressure, the carotid or femoral artery being for this purpose connected with a François-Franck registering manometer and a sphygmoscope, while the respirations were counted by means of a Marey's pneumograph. As is well known the blood-pressure occasionally rises at the commencement of chloroform inhalation and in all cases falls when anæsthesia supervenes. The important, constant, and lasting phenomenon of chloroform inhalation is the fall of the blood-pressure, and the great danger in this form of anæsthesia is the reduction of the blood-pressure below certain limits. Under ether, on the other hand, even when this anæsthetic is given continuously and in relatively large doses, the blood-pressure remains for a long time at about normal or even above normal. In fatal cases of chloroform toxæmia, in certain cases, probably in most, the respiration ceases before the heart's action stops. Many have thought that the stoppage of the respiration was the cause of the stoppage of the heart, so that death under chloroform was really due to asphyxia. Under ether, however, primary heart failure is very rare. Even respiratory failure only occurs, if we omit cases in which mechanical causes for it are present, when the anæsthesia is so profound that the medullary centres are deeply narcotised. In these cases the blood-pressure falls and the mechanism of respiration passes into abeyance owing to the cessation of nerve stimuli from the poisoned centres. In practice these perils practically never occur unless as a result of pre-existing disease or of the oversight of the most obvious signs of danger. Professor Duplay and Dr. Hallion maintain, on the contrary, that in the case of chloroform deaths are never due to failure of the respiration, relying on several arguments, one of which is as follows. When syncope is fully established let artificial respiration be substituted for the natural respiration (currently supposed to be insufficient when the animal is profoundly under the influence of the anæsthetic) and at the same time let the administration of the anæsthetic be continued. If the failure of the circulation which caused the syncope were really due to the anæsthetic interfering with the respiration the syncope ought to be recovered from under artificial respiration, but this, according to Professor Duplay and Dr. Hallion, never happens, for the circulation does not improve and finally stops altogether. M. C. Richet has pointed out that when alarming symptoms are induced by the anæsthetic administered for a surgical operation, artificial respiration and rhythmical traction of the tongue are resorted to the air thereby thrown into the lungs is more than sufficient to prevent death from asphyxia. The real cause of death in such cases is that the cardio-vascular apparatus has been paralysed by the anæsthetic at the same time as are the respiratory centres. Stoppage of the respiration, although not serious in itself, is nevertheless an extremely important symptom, for it indicates the near approach of irremediable interference with the circulation. The patient almost always survives if the anæsthetic is stopped and artificial respiration practised as soon as the natural respiration has ceased, but if at this stage the cardio-vascular apparatus happens to be so affected that the blood-pressure has fallen nearly to zero the case is hopeless. Professor Duplay and Dr. Hallion hope that they will be able before long to describe a method of ascertaining the blood-pressure during surgical operations under anæsthetics.

STREET RUFFIANISM.

WITH the waning of the hours of daylight the Hooligan seems to have taken for his motto the old verse, "Uprise ye, then, my merry men, it is our opening day." His "bag" so far includes a man named Schafer, aged 32 years, knocked down and kicked in Gibraltar-row, Bethnal-green, on Oct. 7th, with the result that he died on Oct. 11th; a boy named Hiscoke, aged 17 years, fatally stabbed in Harwar-street, Kingsland-road, on Oct. 9th; and a man in Hackney killed by a blow on the jaw. To this list may be added an assault upon the landlord of the King's Arms in the Westminster Bridge-road, a murderous assault upon a man named George Acton in Commercial-road, a highway robbery on Hampstead Heath, and two faction fights in Clerkenwell. The inquest upon the body of Hiscoke was held on Oct. 13th, when the coroner's jury returned a verdict of "Wilful murder against some person unknown" and left the matter in the hands of the police. A like verdict was given on Oct. 16th in the case of Schafer. As long as the Hooligan confines himself to pure faction-fighting it would, perhaps, be a pity to stop him, in the hope that by a process of exclusion the contending gangs might gradually be weeded out, but it is a different matter when a gang sets upon an inoffensive passer-by. The law, of course, is to blame, in that the punishment which it inflicts for simple assault, so long as the victim is robbed neither of a few pence nor of his life, is most inadequate. In the former case the assailant gets a long term of imprisonment and possibly in addition a flogging, and in the latter he is, or can be, hanged; but for the ordinary assault a short term of imprisonment is considered enough, and even so magistrates very often do not give as heavy a sentence as they are entitled to. A month or ten days' hard labour, or a trifling fine, which latter is paid by a "whip round" of the gang, is a trivial penalty. It is true that simple imprisonment has no terrors for the rough. There are only two ways of dealing with him—one by inflicting physical pain, the other by making him work, and work hard. All perpetrators of brutal assaults should be soundly flogged. It would be a good thing, too, as was suggested by one of the morning papers, to levy a sort of blood tax upon the inhabitants of the district in which such outrages take place. A vigilance committee would doubtless be formed and very soon the Hooligan would find the district too hot to hold him. But though no mercy should be shown to the full-blown Hooligan the tender shoot of the same plant should be treated with consideration The growing boy in London is beset with temptations of every kind, and, despite the enormous sums wasted by the school board in giving an education which they were never meant to give, there are far too many truants. Neither are parents blameless in the matter. As was well shown, however, by a correspondent of the *Times* of Oct. 15th, it is the fatuous way in which the school board selects cases for prosecution for non-attendance which feeds the criminal classes. Mr. C H. Eliot, the writer of the letter, puts the case very clearly as follows :—

> "For instance, guided solely by the registered attendance, the board will apply for a summons against the widow whose eldest son has left school a few weeks too soon, to take advantage of a promising opening and help his mother; while the young *gamin* of 11 who is fast learning the life of the streets escapes for months, and often altogether. Here is the reason. The boy who catches the infectious wandering instinct so common among London boys begins by staying out late at night; then he is away from home all night; next, after an interval of regular school attendance (he is a sharp lad), he is out for three nights; then, after another interval, a week; then a fortnight. During all this time his attendance is but little below the average demanded, and no inquiry is made. So he will go on for months, and then perhaps he is convicted of stealing. All the time he has been an associate of thieves and so becomes one himself. The school board has never found it out, because his average attendance was good enough. But all the time he is a criminal in the making, and it is obviously better that the law should be enforced against him and his parents than against the respectable son of the widow who leaves to help his mother"

Prevention is better than cure: by all means let the murderous rough meet with due punishment, but let us do what can be done to stop him in the making. It is fair to add that a letter appears in the *Times* of Oct. 18th from Sir C. A. Elliott directly traversing Mr. C. H. Eliot's statements.

POST-OPERATIVE HÆMATEMESIS.

The *Boston Medical and Surgical Journal* of Sept. 27th contains an important paper by Dr. K. Winslow on this obscure subject. Post-operative hæmatemesis is not described in the text-books and is scarcely recognised in surgical literature. In his lectures on the Surgery of the Stomach Mr. Mayo Robson[1] alludes to the subject. He states that he has observed hæmatemesis after operation in cases of intestinal obstruction and tuberculous peritonitis, and after cholecystotomy, choledochotomy, herniotomy, ovariotomy, and simple exploratory laparotomy. Two cases were fatal. In one case cholecystotomy was performed under cocaine for cancer of the common bile duct Violent hæmatemesis set in on the day after operation and proved fatal in three days. At the necropsy nothing was found in the stomach to account for the bleeding. Dr. Winslow relates the following case. A very stout woman, aged about 65 years, had for many years an umbilical hernia as large as an infant's head. Vomiting and colic occurred, which lasted six hours Unsuccessful attempts at reduction were made by taxis and ice bags. Under ether an elliptical incision dividing all the structures in the abdominal wall down to the peritoneum was made, according to the method of Condemin. The peritoneum was opened on the left side and the finger was introduced into the hernial ring from the abdominal cavity. The sac was completely divided from within by a transverse incision through all the tissues The contents—the transverse colon, the small intestine, and the omentum—were exposed. There were many adhesions which were readily separated. A small portion of the omentum was ligatured and removed. The whole sac was excised. The wound was approximated with difficulty and was closed by interrupted silkworm-gut sutures passed through all the layers of the abdominal wall The operation occupied a little over an hour and the patient rallied well. Some vomiting followed but progress was satisfactory. The temperature rose a degree on the second day, but fell to 99° F. on the third. In the evening the patient began to vomit. The nurse noticed for the first time that dark fluid was coming up. About midnight the patient vomited an enormous quantity of dark blood and then suddenly died. At the necropsy much dark clotted blood was found in the stomach and intestines, but no lesion was discovered. There was no evidence of infection. The wound had healed by first intention. A typical instance of post operative hæmatemesis is recorded in this issue of The Lancet by Mr. Mansell Moullin. A young man, aged 23 years, died from hæmatemesis within 48 hours after a small incision into the left iliac fossa The cause of post opeatrive hæmatemesis is unknown. Vomiting after the anæsthetic will not account for it, for it has occurred in cases where such vomiting was absent. Eiselberg, however, seems to have established some connexion between it and injury of the omentum. In six cases observed by him the omentum was ligatured. In an experiment on an animal multiple hæmorrhages into the stomach followed twisting of the omentum. But Rodman failed to get this result in four experiment. He believes that sepsis is the cause of the hæmatemesis, since sepsis favours disintegration of red corpuscles and the gastric mucous membrane is specially liable to congestions. As to treatment, Mr. Mayo Robson recommends free purgation with calomel and rectal feeding. He has not ventured to operate because the indications were not clear and the patients were not, as a rule, fit to bear a second operation.

FATIGUE PRODUCTS.

The eating of "high" game is undoubtedly attended with risks and the poisonous effects are probably due to the toxins produced in the earlier stages of the putrefactive process. The advantage, of course, of hanging game is that the flesh becomes tender and decidedly more digestible than when it is quite fresh. The ripening process, however, may mean the elaboration of toxins. It has been stated that the production of the characteristic flavours of game is related directly to the amount of sulphuretted hydrogen or sulphur-alcohol set free, but it is rather repulsive to think that the delicate flavour of game is dependent upon that invariable product of decomposition of rotten eggs—sulphuretted hydrogen. The smell evolved during cooking of "high" game is even more disgusting. It is a curious fact, however, that game can be made to look "ripe" and green by injecting into the fresh flesh potassium sulphide. The poisonous properties of high game are probably not due to such simple putrefactive products but rather to very complex bodies possibly of the nature of alkaloids. Fresh game, however, sometimes sets up mysterious poisonous symptoms which have been attributed to the fact of the game having been over-hunted and fatigued. Fatigue products indeed have been separated from over hunted game which, when injected into a healthy animal, have produced marked poisonous effects There is no doubt that fatigue products under certain circumstances are also elaborated in the human body and give rise to a species of self-poisoning, characteristic symptoms of which are headache, stupor, and gastric and intestinal pains The flesh of over driven [illegible] Liebig, [illegible] of a [illegible] been caught in a snare gave rise to symptoms of poisoning when partaken of. Again, fatal results ensued when pigs were fed upon the flesh of a horse which had died during its struggles when being broken in This curious formation of poisonous products in the flesh of animals through a state of terror or exhaustion is a question well worth considering in relation to the wholesomeness of animal foods and emphasises the importance of slaying animals intended for food in the most humane way and without inducing terror or fatigue

---

THE ALVARENGA PRIZE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA

[illegible] will be made on July 14th, 1901, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered Essays intended for competition may be upon any subject in medicine, but must not have been published and must be received by the secretary of the College on or before May 1st, 1901 Each essay must also be sent without signature, be plainly marked with a motto, and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author It is a condition of competition that the successful essay or a copy of it shall remain in the possession of the College, other essays will be returned upon application within three months after the award The Alvarenga Prize for 1900 has been awarded to Dr David De Beck of Cincinnati, Ohio, for his essay entitled "Malarial Diseases of the Eye"

THE GENERAL ELECTION.

THE General Election has now (with one exception) decided who are and who are not to represent the country in Parliament, and we have to congratulate the following members of our profession upon their election —R Ambrose, L R C P & S Edin (Mayo West), John Dillon, L R C S Irel (Mayo East); Sir R B Finlay, Q C who was at one time a medical practitioner (Inverness Burghs), R Farquharson, M D Edin (Aberdeenshire), Sir M Foster, K C B M D Lond (London University), Sir W Foster, M D Erlang, L R C P Lond (Derbyshire, Ilkeston), F Rutherford Harris, L R C S Edin (Monmouth District), M A MacDonnell, M D R U I (Queen's Co Leix), R J Price, M R C S Eng, who like Sir R B Finlay, long since deserted the profession of medicine for that of the law (Norfolk East), C K D Tanner, M D, M Ch R U I (Mid Cork), and Sir J Batty Tuke M D Edin (Edinburgh and St Andrews Universities) With the exception of Mr Rutherford Harris whose connexion with the British South Africa Company is well known, all these gentlemen were members of the preceding House of Commons Sir Charles Cameron, we regret, did not seek re election at the hands of his Glasgow constituents The following medical candidates were defeated G B Clark M D, F R C S Edin, J Court L R C P Lond, M R C S Eng, A Conan Doyle, M D Edin, J I Fox, M D Univ Cincinnati, F R C P Kingston, Canada, A P Hillier, M D Edin, J King Kerr M D R U I, Chas O'Neill, M D R U I, V H Rutherford, M B Cantab L R C P & S Edin, E C Thompson, M B, T C D, F R C S Irel, and Sir George Pilkington, M R C S Eng, L S A Of these Dr Clark Dr Fox and Sir George Pilkington sought re election Mr Marshall Hall, Q C, who has been returned for the Southport division of Lancashire, defeating Sir G Pilkington, is a son of the late Dr Alfred Hall of Brighton who attended the late Mr Wakley, M P, the Founder of THE LANCET

BACTERIOLOGICAL DIAGNOSIS AND ITS RESULTS

THE Islington Vestry has set a good example to other vestries in offering to examine the sputum and blood of persons suspected to be suffering from diphtheria phthisis, and enteric fever In the second quarter of this year in 57 instances medical practitioners availed themselves of this valuable offer The results are interesting In regard to diphtheria 19 *examinations were made*, of which eight resulted in a positive diagnosis and 11 in a negative, in regard to enteric fever the blood of 21 persons was examined, in four cases it gave positive results and in 17 negative, in regard to phthisis, the sputum was examined in 17 instances and the bacilli were discovered in only seven specimens The medical officer of health gives the figures of the Jenner Institute for each of these diseases in the examinations since 1898 Of 171 cases suspected of diphtheria the results were negative in 95 Of 161 cases of supposed enteric fever 93 were negative, of 127 cases *examined for tubercle 70 were negative* The public provision made by the Islington Vestry follows logically from the Notification and Isolation Acts and will be much appreciated by the profession until bacteriological work is simplified

AT the funeral of the late Mr J F France, formerly ophthalmic surgeon to Guy's Hospital whose death we announced last week, the Royal Medical Benevolent College was represented by Dr C Holman, the treasurer, and Mr J Bernard Lamb, the secretary, while the Royal Asylum of St Anne's Society was [illegible] the secretary The lat[illegible] presentations for fema[illegible] presentations being he[illegible] school of St Anne's S[illegible] tioners being entrusted by deed to the Council of Epsom College

THE first meeting of the session 1900-1901 of the Odontological Society of Great Britain will be held at 20, Hanover-square, W, on Monday, Oct 22nd, when the President, Mr John Ackery, will deliver his inaugural address The chair will be taken at 8 P M Casual communications will be given by Mr Walter Harrison, on Abnormal Roots; Mr Sim Wallace, on Twisted Roots, and Mr W A Rhodes, on the Mechanical Treatment of Superior Protrusion Mr A F Baker will show and present to the museum some interesting old operating instruments

THE death is announced, at the age of 61 years, of Dr. David Young, formerly resident in the Via Venti Settembre, Rome The deceased was M D of the University of Aberdeen and a Fellow of the University of Bombay and also Examiner in Midwifery For some years he was, in addition, Professor of Botany at Grant Medical College He was the author of a work upon Italian climatology called "Rome in Winter and the Tuscan Hills in Summer"

AT the opening meeting of the Cardiff Medical Society, held on Oct 12th, Dr Edward Walford read his presidential address upon Reforms in the Procedure of Death Certification Dr W G Savage gave some interesting details of the methods which were adopted in the bacterioscopic examinations conducted in connexion with the fatal case of plague which recently occurred in the Cardiff Sanatorium

THE medical service in state at St Paul's Cathedral under the auspices of the Guild of St. Luke was held on Oct. 17th. The Bishop of Rochester preached the sermon and the London Gregorian Choral Association—the choir consisting of 300 voices—rendered the musical part of the service in a most impressive manner.

WE regret to learn that Professor A. W. Hughes of King's College, chief superintendent of the Welsh Hospital, now returning home on board the *Saxon*, is suffering from an attack of enteric fever. He is reported to be progressing favourably.

ON the occasion of the Annual Public Night of the Medical Society of University College, London, held in the College on Wednesday evening last, an interesting address was given by Dr. Judson S. Bury on Bias in Clinical Medicine.

THE London County Council have issued a circular drawn up by Mr. James Cantlie upon the signs and symptoms of plague for the use of metropolitan medical practitioners. We shall notice this circular at length next week.

A REUTER'S telegram of Oct. 9th from Brisbane states that a fresh case of plague has occurred there.

THE WAR IN SOUTH AFRICA.

WE are still compelled to speak of the war in South Africa, although it cannot any longer be properly called so, for it has degenerated into a species of what was termed in the last Burmese war, dacoity. The remains of the dispersed Boer forces, aided and abetted by a friendly and sympathetic Boer population, continue to make raids in various directions, to wreck trains and interrupt communications, and to do everything in their power to harass the British forces. The extent of territory conquered and occupied by the Queen's troops, the nature of the country, the length of the railway and telegraphic communications, and a disaffected population, all lend themselves to operations of this irregular kind. The news during the past week is indicative of a recrudescence of a feverish activity on the part of the enemy. Lord Roberts has postponed his own departure and has delayed that of some of the colonial troops until things shall have assumed a more settled and satisfactory aspect. However annoying the present state of things may be it cannot be said to have been unexpected, and the situation has to be faced and overcome. While enteric fever has become far less prevalent than it was there is still a good deal of dysentery—happily of the mild catarrhal and more easily treated form, as a rule—among the troops in the field. The army, as a whole, however, is healthy and in excellent spirits. Lord and Lady Roberts inspected the Langman Hospital at Pretoria on Oct. 19th. Transports with invalids from the seat of war are frequently arriving in this country, and, as a rule, the health of the sick and wounded has been greatly benefited by the voyage.

The Boer prisoners at St. Helena are healthy. Very few of them are in hospital at the present time. Among the deaths that have recently occurred three have been from tuberculosis.

When the history of this war comes to be written the very gallant and plucky defence made by a small force of colonial troops shut up at Elands river camp, Brackfontein, will form one of its brightest pages. Not only is that the opinion of those acquainted with all of the circumstances but the correctness of their judgment has been since ratified and corroborated by Lord Roberts himself in highly appreciative terms. A brief statement of the facts is well worthy of being put on record. The force, composed of Australians and Rhodesians, consisted of 22 officers and 480 men under the command of Colonel Hore. They had with them one small 7-pounder muzzle-loader gun (for which there were only 100 rounds of ammunition) and two Maxims and a large quantity of provisions and stores. It appears that the small garrison held a smoking concert in camp on the night of Aug. 3rd. Early on the following morning the troops were awakened by the bursting of shells in their camp, which covered about four acres on a kopje, and they soon found themselves in a very tight place as they were surrounded by a Boer force estimated at 3000 under the command of Delarey. The only medical officer present with the besieged garrison was Captain Albert Duka, Army Medical Corps, Queensland Defence Force, who had volunteered and had been selected to accompany the Australian contingent to the seat of war. We are indebted to his father, Surgeon-Lieutenant-Colonel Duka, a retired officer of the Indian Medical Service, for the opportunity of reading a communication from his son written from Mafeking, whither he had proceeded after the relief of the besieged garrison at Elands river. We cannot do better than adhere closely to the interesting description of the siege given in this communication. Captain Duka's experience of the war was probably unique. The shelling of the camp began on the morning of August 4th and went on all day. There were 32 casualties, nearly all of which (26) were severe shell-wounds. He was told that there were 1800 shells sent in on that day and 700 on the next; then, either because the Boers were running short of ammunition or because the fighting part of the garrison were disappearing underground, the Boer fire became less lively, although not a single man could move across the square and show his head across the breastwork without having a large number of bullets fired at him. This sort of thing went on for 12 days, when Lord Kitchener arrived with his division. The Boers evidently knew that he was coming and they withdrew their guns two days before, but kept the besieged quiet by sniping. Captain Duka adds that he had no one to assist him who had had any previous training. His hospital consisted of three ambulance wagons and a small four-feet high parapet formed of biscuit boxes round two sides of it. After the second day of the siege, and when the men could be spared for the work, which was all done at night, this parapet was raised another two feet and strengthened by earth and stones thrown up at the back of the biscuit boxes. He had over 70 casualties altogether, five men being wounded in hospital a second time by shells bursting inside it. All the wagons were much knocked about, but Captain Duka fortunately escaped being hurt and was able to carry on his work throughout. There were 73 killed and wounded (51 whites and 22 natives). The great majority, 65 per cent., of the wounds were from shells, and he performed three amputations and had 48 other operations, such as the extraction of bullets, fragments of shell, &c. It must have been very gratifying to this medical officer to find himself on the day after the relief of the garrison presented by the men with the only new pipe in the camp with an inscription cut on the bowl of it and to have heard their cheers in token of their sense of the work which he had done. Nearly all the horses and cattle belonging to the force were killed during the siege. General Carrington, it will be remembered, had previously proceeded to the relief of the very hard-pressed garrison but had been unable to achieve his object. As indicative of the topographical and other difficulties of the country Captain Duka remarks, *à propos* of the attempts to surround De Wet: "In the country we are in it is no wonder that the generals cannot catch De Wet and others, as there are any amount of parallel, or nearly parallel, valleys. One day a patrol of 70 men was out; the Boers knew where we were going and sent 200 men of Delarey's force with a quick-firing gun to catch us, but we came back by another road and although it was only two miles off as the crow flies they either did not know we were passing or could not get at us." It is not hard under such conditions to realise the ease with which the Boers, who know every inch of the country, can elude us. Again, "The reason why convoys are lost is because too few men are in charge, or, as in our case, mounted troops without guns are left to take care of large stores, and although they may manage to keep the post and stores they become practically useless as their horses are destroyed and their mobility lost." In the case of the Elands river the difficulty of the defence, had the siege been prolonged, would have been want of water. There was an ample supply of stores with the force and it was the anticipated capture of these no doubt that led to the attack being made. The Boers never risk fighting in the open if they can help it, but usually keep at a long distance

1500 yards) off, unless they can secure a strong kopje and vell protected position.

MALARIAL EPIDEMIOLOGY.

A FURTHER "Contribution to the Study of the Epidemiology of Malaria in the Light of Recent Views of its Etiology," by Professor A. Celli, appears in the *Supplemento al Policlinico*, anno vi., No. 48 Researches have been carried on not only on the estate of Cervelletta in the Roman Campagna, but at various other stations in different parts of the Italian peninsula—namely, at Trinitapoli in the province of Foggia, at Argenta near Ferrara, at Mantua in the Ospedal Maggiore of Milan, and at Cumignano in the province of Cremona Observations were also made in several localities in the province of Novara (Trecate, Cerano, Vercelli, Asigliano), and in the Alpine valley of Sondrio. In this way Professor Celli was enabled to control the facts elicited by a study of the statistics and clinical reports of large hospitals, such as those of Vercelli, Novara, Mantua, and Ferrara, by observations in the Campagna and at the homes of the patients themselves. He was thus able to study not only the mild cases which never find their way to a hospital, but also those which are treated at home and those occurring among persons who leave after the field work is over. Note was taken of the following points 1 The distribution of the malarial parasite in the peninsula exclusive of Latium. 2 The occurrence of multiple infections and of relapses 3. The relations of the epidemic with mosquitoes, with agricultural life, and with the temperature.

As regards the first of these, parasites of malignant forms predominate in the provinces of Foggia and Salerno as they do in the Roman Campagna. Professor Celli was surprised to find them also common in the valley of the Po where malaria of the summer autumn type is distinguished by the peasantry as "August fever," although by medical men, including even Golgi, its existence there was not admitted He was still more surprised to find a spot in the Alpine valley of Sondrio where at the middle of September all the fever cases were of this grave type The plain of the Adda in the Lower Valtellina, at an elevation of from 400 to 700 metres, formerly very malarious, still has foci of disease—as, for instance, at [illegible] ere were bad autumn tertians [illegible] rsh larvæ of mosquitoes were [illegible] grave tertian forms, with a [illegible] which they present in the Roman Campagna, are common in the valley of the Po the cases, so numerous in Latium, of deadly pernicious malaria are rarely met with. The free use of quinine probably explains this scarcity of pernicious cases, although it has been powerless to diminish the zone of diffusion of malaria in general

The occurrence of multiple infections—that is, of two or [illegible] observed very frequently. [illegible] reat importance, is that of [illegible] listinguished from pseudo-relapses where we have to deal not with a relapse proper but with a fresh infection of a previously malarious patient. The distinction is not yet possible in the mild tertian, but in the quartan a diagnostic guide is afforded by the fact that gametes are very abundant in the circulating blood of true relapses, whereas they are absent or extremely scarce in the pseudo-relapses. In autumn tertian the differential diagnosis is still easier, the successive attacks of true relapses gradually diminishing so much in force that the patient is able to walk about during their occurrence, whereas a new infection always prostrates, even when the patient has previously suffered from malaria. In true relapses semilunar bodies are present, while they are never found in primary infections. It is interesting to note the course of true relapses in the different types of fever and in the various months of the epidemic year, which Professor Celli claims he has shown to extend from one summer to the next When the fresh infections of autumn tertian come to an end in October, as happened last year, they are at their maximum in August and September, gradually declining in number through June and July. The relapses of quartan, on the contrary, gradually increase in frequency from October on into July and August, and the summer-autumn tertian re commences before the quartan, which in Latium, as well as in northern and southern Italy, is the last to yield relapses and the last to begin them. The mild tertians have their maximum of relapses in the spring, as may be well seen in Lombardy, where they precede the development of grave tertians in June Why the period for the relapses of summer tertian should not correspond with the approach of its epidemic year, as is the case with quartan and spring tertian, has not yet been made clear Long intervals may elapse between the relapses of summer tertian and of spring tertian Quartan is more persistent and continuous in its relapses in spite of the use of quinine

As to the relation between mosquitoes and epidemics of malaria, Professor Celli found anopheles wherever there was fever. The commonest variety was the anopheles claviger, but in the neighbourhoods of Ferrara and Vercelli the anopheles pictus and the anopheles pseudo-pictus were also abundant, and in the alpine zone the anopheles bifurcatus The presence of anopheles was, however, noted in localities which were perfectly healthy and at great altitudes where malaria had never been known These insects may therefore be conveyed with man and his belongings, hay, animals, vehicles, &c, far from genuine malarious centres; and hence the geographical distribution of anopheles cannot coincide with the geographical chart of malaria Consequently it cannot be asserted absolutely that the anopheles is always and of itself a sure indication of malaria But wherever anopheles are present, and there are men with malarial gametes in their blood whom they can bite, and where at the same time the temperature is suitable for the development of the parasite in the mosquito's body, it may be confidently predicted that an outbreak of malaria will occur In this respect epidemiological studies confirm the experimental observations of Ross, Grassi, Bignami, and Bastianelli on the multiplication in the middle intestine of the anopheles of the parasite of human malaria and on the negative rôle played by the culex in the propagation of this disease The city of Mantua offers a typically demonstrative instance of this fact, its central part being infested by culex but quite free from malaria, while in some quarters at its periphery where there are innumerable anopheletes in the houses and larvæ of anopheles in the neighbouring lakes and ditches a severe epidemic of malaria has prevailed during the last two years

It is interesting, Professor Celli remarks, to note the relation in various particulars between malaria and agriculture. Epidemics may arise in connexion with the cultivation not only of the essentially malarial crops such as rice, but also of crops in themselves dry and healthy, when these latter demand the presence of work-people during the unhealthy months for the reaping and threshing of wheat, the harvesting of maize, and the cultivation and ingathering of beetroot Professor Celli distinguishes two epidemic types. To the one, with its minimum number of cases in June, belong the epidemics of Milan, Pavia, Crema, and Ferrara, and this type is, therefore, specially connected with irrigation crops; to the other, with its minimum of cases in January and February, belong those of Rome, Cagliari, Vercelli, and Mantua In the first case the epidemic, mostly of mild tertian, commences in June with the cleaning of the rice and reaches its height during the reaping and threshing, when the "August fevers" above mentioned are at their maximum. In the second type the fevers are rare in June, more common in July, and reach their maximum in August after the threshing season When the summer is prolonged, and in the warmer zones such as the Pontine Marshes, the harvesting of [illegible] and October gives rise to a late epidemic. [illegible] of beetroot under very insani- [illegible] ugment the malaria epidemic. The tanks for the maceration of textile plants (hemp and flax), with their collections of stagnant or nearly stagnant water, by favouring the development of mosquitoes likewise favour that of malaria The process of maceration itself, regarded as so dangerous that special sanitary regulations are in force regarding it, has, Professor Celli believes, a contrary effect by destroying or retarding the growth of larvæ

Finally, with regard to the relation between the atmospheric temperature and epidemics of malaria, Professor Celli says that it would appear that the latter must be preceded and accompanied by a temperature of about 25° C. (77° F) but on this point he reserves any definite opinion for the present.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on Oct. 11th, the President, Sir **WILLIAM MACCORMAC**, Bart., K C.V O., being in the chair.

The **PRESIDENT** reported that Dr. Alexander MacCormick, M.R C.S. Eng., Lecturer on Surgery in the University of Sydney, N S.W., and recently a consulting surgeon to H.M. Forces in South Africa, had, owing to a capture of the mails by the Boers, not received the invitation of the Council to attend the centenary festival for the purpose of receiving the diploma of Honorary Fellowship. Dr. MacCormick was then elected to the Honorary Fellowship and was introduced and admitted an Honorary Fellow.

The **PRESIDENT** reported that a letter had been received from the Secretary of State stating that Her Majesty the Queen had graciously received the address of condolence from the College on the death of H.R.H the Duke of Saxe-Coburg and Gotha.

It was resolved that the first volume of the Catalogue of the Physiological Series of Comparative Anatomy be offered for sale at 12s. a copy.

The Council adopted the report of the Finance Committee and passed the balance sheet which had been approved by the auditors. The chief points in the report are as follows. The gross income of the College for the past year was £25,211; this is an increase of £500 on the income of the previous year This increase was chiefly due to an advance in the amount of the fees from the examinations for the Diploma in Dental Surgery as a result of an alteration in the fee for the diploma, but in future years the effect will not be so marked, as under the new rules fees are no longer returned to unsuccessful candidates. The fees from the examinations of the Conjoint Examinations Board had diminished by £1094, and the falling off was most marked in the case of the third examination. As the expenditure for the year only differs from the amount of the previous year by £6 there is a credit balance of £1645 on the year. The extraordinary expenditure amounts to £999 and is £453 heavier than the previous year. It includes the costs of the Crown in the appeal respecting the taxation of the College, payment of Corporation Duty for five back years, and the fees for the new charter.

With regard to the regulations relating to the fees for the diploma of Fellow adopted by the Council on July 25th, 1900, the committee are of opinion that some modification is desirable in the case of candidates who commenced their course of examination before that date. The regulations previously in force contained the following provisions, viz. :—

> Provided always that no candidate for the diploma of Fellow shall be required before admission to examination or otherwise to pay altogether more than 30 guineas, and that the moneys paid by each candidate and retained as aforesaid shall be treated as the fee payable and paid by such candidate on admittance to the diploma of Fellow.

The committee think it right that candidates who entered for the examinations for the Fellowship under this condition should be allowed a reasonable time in which to obtain their diplomas without any alteration of the condition, and they accordingly recommend the Council to adopt the following regulation, viz. :—

> Candidates who have presented themselves for examination for the diploma of Fellow under the regulations in force before July 25th, 1900, will not be required to pay altogether more than 30 guineas in examination and admission fees, provided that they become qualified to receive the diploma of Fellow before October 1st 1902, or within 10 years from the date of their registration by the General Medical Council as medical students.

The Council elected Mr. Arthur S. Underwood a member of the Board of Examiners in Dental Surgery (Dental Section). Mr. J. Langton was elected a member of the Committee of Management in the vacancy occasioned by the retirement of Mr. T. Bryant. Mr. H. Morris was re-elected a member of the Laboratories Committee The Council nominated Mr. Alfred George Sworn as the eighth Jenks Scholar. Mr. Sworn was recently a student at Epsom College and is now a student at University College, London.

The arrangements for the Cartwright Medal have been completed and a scheme has been drawn up for its award; its chief provisions are as follows. The prize shall consist of a medal and a sum of money which are to be awarded quinquennially for the best essay on a subject previously selected by the Council. Candidates for the prize must be persons engaged in the study or practice of dental surgery and possessing qualifications capable of [illegible] the Medical Acts of the United Kingd

A Member of the College has been called upon by t Council to show cause why he should not be removed fro the roll of Members on account of his connexion with t "Drouet Institute," and the attention of the Gener Medical Council was directed to the advertisements of person who has illegally assumed the description "R D (R.C S Eng.)," and they were requested to take the matt into consideration with a view to action under Section of the Dentists Act, 1878.

The **PRESIDENT** reported on behalf of himself and t Vice-Presidents that in pursuance of the resolution of t Council on July 25th last they had addressed a letter to t Marquis of Salisbury again urging his lordship to appoint departmental committee to inquire into the prevalence an treatment of venereal disease among the civil population this country, and a reply was read stating that the subje would receive the consideration of Her Majesty's Government.

A vote of thanks to the Centenary Committee was carrie

THE OPEN-AIR TREATMENT OF CONSUMPTION.

A CONFERENCE of the representatives of Poor-law authorit in the metropolis was held in St. Martin's Town Hall o Oct 15th to consider the question of establishing hospital for the open-air treatment of consumption.

Mr. J. Z. **CAHILL**, the chairman of the Poplar an Stepney Sick Asylum District Board, presided and there wa a very large attendance of delegates, including medical men Members of the National Association for the Prevention of Consumption were also present, as was Dr. Downs o the Local Government Board, who was not present in a official capacity. The secretary read the following lette which had been sent to the various Poor-law authorities by the Poplar and Stepney Sick Association District Board

> For some considerable time the Board of Management have ha under consideration the subject of the open air treatment of phthisis with a view to the establishment of a hospital for the special care o such cases. The managers are of opinion that by the proper treatmen of the disease in its early stages much good would result to the patient; in many cases probably a permanent cure would be effected, and they are convinced that this would be best achieved and maintaine by the open-air method now being advocated in so many quarters. In the Poplar and Stepney District Sick Asylum on a recent occasion there were 65 phthisical cases, many of which would in the early stages of the disease probably have derived much benefit, if not actual cure, could they have had the advantage of the open-air treatment of their ailment when in its incipient stage After a conference with the representatives of the boards of guardians and medical officers and clerks of the unions comprising the district the question has taken a more practical form and has resulted in a deputation of the managers waiting on the Local Government Board on the subject In receiving the deputation the Local Government Board expressed its sympathy with the managers in their desire to provide the class of accommodation referred to, but objected to the managers taking individual action in the matter, the question, in the Board's opinion, having a metropolitan rather than a local character, and, entertaining this view, the Board intimated that provision, if made at all, should be for the metropolis as a whole and be under the management and control of a metropolitan authority. The Board also suggested that if th [illegible] to pursue the matter further a conference [illegible] Poor-law authority in the metropolis should [illegible] discuss the subject, and in the event of such [illegible] the provision of the proposed accommodation desirable it should address the Local Government Board on the subject and thus give the views [illegible] generally on the question. The managers will feel [illegible] kindly bring the matter under the notice of your [illegible] to a conference being held to discuss the subject ...

Dr. J E. **SQUIRE** said that facts furnished a strong argument in favour of a combined effort on behalf of the London Poor-law guardians to give more effective treatment to the consumptive poor, the proportion of this disease among the inhabitants of the metropolis being greater than in other divisions of [illegible] The habits of life of the po [illegible] in this respect were [illegible] but also to other members o [illegible] point to notice was that by the sanatoria treatment, whilst giving to individuals the best chance of recovery, the importance of hygienic living was impressed upon them and a knowledge of hygiene was likely to be more widely spread.

Dr. **NATHAN RAW** gave a brief outline of what had [illegible] done in Liverpool and the success which had attended [illegible] efforts of the Poor-law guardians in the sanatoria treatment

Mr. J. H. **RUTHERGLEN** (clerk to the Kensington Guar urged that the number of phthisical patients chargeable the various boards in London should be estimated and that the [illegible] ment to voluntary notification [illegible] which tended to remove the [illegible] able to consumption would al[illegible] other diseases [illegible]

Dr. BURTON-FANNING gave his experiences with regard to the open-air treatment of consumption, which were very satisfactory, and suggested that as an experiment rural infirmaries, where he was of opinion that 25 per cent. of the beds were unoccupied, should be utilised as sanatoria.

Dr. A. H. DOWNS, medical inspector to the Local Government Board, strongly supported the movement, pointing out the various advantages which would result from such treatment of the phthisical poor as was advocated.

Mr. B. A. LYON (Hampstead) submitted the following motion:—

> That this Conference of Poor-law authorities, having discussed the question of the open air treatment of [illegible] that the time has come when provision [illegible]

This was seconded by Mr. J. O'CONNOR (Stepney) and carried *nem. con.*

Several speakers having expressed the hope that no new board should be formed to carry out the proposed suggestion the following sub committee was appointed to form a deputation to the Local Government Board: Mr. J. Z. Cahill, Mr. B A. Lyon (Hampstead), Mr. E. Smith (Bethnal Green), Mr. E. A. Barton (Kensington), Mr. R. P. Long (St Pancras), and Mr. W. J. Wentenhall, J.P. (St. Pancras)

A vote of thanks to the Chairman terminated the proceedings.

THE PLAGUE.

PRECAUTIONS AGAINST PLAGUE IN LONDON.

THE occurrence of a suspected case of plague in London has served a purpose in demonstrating that the metropolis has not been unmindful of the duties which may have to be performed in the event of this disease appearing among its population. The London County Council have, as already announced, been asked by the Local Government Board if they are prepared to make provisions for "contacts" or families in which a case of plague has occurred. It would appear that the communications between the Local Government Board and the Council have proceeded a step further than could be understood by the report of the Public Health Committee of the Council which we published in THE LANCET of Oct. 13th (p. 1092). A man in East London was suspected to be suffering from plague. The medical officer of health of Limehouse was immediately notified of this case, the medical officer of health of the county of London was duly informed, and the County Council's machinery was at once brought into operation. Mr. James Cantlie, who had been retained by the Council for such purpose, at once [illegible] symptoms at the time being [illegible] was sent to Dr. Klein for [illegible] The patient was removed to a [illegible] in their possession and which [illegible] h cases and safely isolated there pending further investigation. Fortunately, Dr. Klein's examination has conclusively proved that his malady is not plague, but this occurrence has demonstrated the foresight of the Local Government Board and the London County Council in making provision before recognised plague is present in London. Our story would not be complete if we did not refer to the other steps taken to protect the population against risk of infection from this disease. The r[illegible] and complete [illegible] Limehouse D[illegible] which his tenement formed a part were kept under constant inspection, and every care was taken to insure that any extension of the disease should be known at its beginning. Although this man has not suffered from plague his illness has sufficed to show what is London's machinery for dealing with cases of plague. The only authority whose services were not needed in this particular case was the Metropolitan Asylums Board, but there is no doubt that if actual plague had been in question the patient would have been at once removed to one of the Board's hospitals. It may be said that London suffers from division of authority, but when all authorities work in accord the public is well protected. We may congratulate Mr. G J Cooper, the chairman of the Public Health Committee of the London County Council, on the fact that the present case of illness, although not plague, has shown that the necessity of being prepared has been well recognised by him and by his committee. The memorandum on plague by Mr. Cantlie, which the Council has prepared for medical practitioners and which was published on Oct. 17th, will serve a useful purpose

Dr. J. F. J. Sykes, medical officer of health of St. Pancras, has issued a circular to all medical practitioners in his district in conformity with the instruction of the Local Government Board, telling them what to do in case they encounter a case which may be plague. A personal letter has also been prepared which is forwarded to passengers who have been reported by the port medical officer of health as arriving by sea from plague-infected ports and as being resident in St. Pancras.

PLAGUE IN SOUTH WALES.

The Llandaff sanitary authorities are to be warmly congratulated upon the manner in which they have grappled with the plague. It will be remembered that one fatal case occurred in Cardiff, the patient being a man who had arrived in the Tyne from Rosario and had travelled overland to Wales. The body was cremated and no fresh cases have occurred. Death took place on Oct, 4th, and as the incubation period of plague is at the outside 10 days the Customs authorities have given the port of Cardiff a clean bill of health.

PLAGUE IN SCOTLAND.

The Local Government Board for Scotland have forwarded to the various sanitary authorities in Scotland copies of three chapters of the "General Sanitary Regulations for the Prevention of the Introduction and Propagation of Plague," adopted by the Venice Convention of 1897. The three chapters deal with "Measures to be Taken in Europe," "Disinfection," and "Preventive Measures on Board Ship"—No fresh cases are reported from Glasgow.

THE MEDICAL GUILD.

THE following is the report of the Medical Guild on Hospital Reform which we have received from the honorary secretary of the Guild, Dr. Arnold W. W. Lea:—

> The Medical Guild is impressed with the difficulties surrounding this [illegible] that reform lies along the lines indicated by [illegible] ss or otherwise of the various [illegible] ir hospitals. The fitness must [illegible] ional or medical exigencies as [illegible] nt methods of investigation [illegible] come within the sphere [illegible] could be better carried out by other means.
>
> The guild regrets that a large amount of hospital abuse is due to medical practitioners, who, particularly in country districts, send [illegible] could afford to do without medical charity.
>
> [illegible] from patients should [illegible] be discontinued and [illegible] more suitable arrangements made.
>
> G. A. WRIGHT, Chairman.
> WILLIAM GRAHAM, Convener.
> ARNOLD W. W. LEA, Secretary.

Obituary.

SIR HENRY WENTWORTH DYKE ACLAND, BART., K.C.B., M.D. OXON., F.R.C.P. LOND., F.R.S., &C.,

LATE REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF OXFORD, HONORARY PHYSICIAN TO H.R.H. THE PRINCE OF WALES, AND RADCLIFFE LIBRARIAN, &C.

WE deeply regret to announce the death of Sir Henry Acland, which occurred at his residence in Oxford on the evening of Tuesday last. The distinguished physician had been in feeble health for some time and the end was not unexpected.

SIR HENRY WENTWORTH DYKE ACLAND, BART., K.C.B., M.D. OXON., F.R.C.P. LOND., F.R.S.

Henry Wentworth Dyke Acland was born on August 23rd, 1815 He came of an ancient line of Devonshire squires a mention of whom is found in the archives of the reign of Henry III., and previously to this there is no doubt that the family of Acland was, even in Saxon times, of considerable note among the notabilities of the western counties. Sir Henry Acland's father, Sir Thomas Dyke Acland, was a Member of Parliament for the county of Devon and throughout the long and distinguished history of the family there have been many instances in which Aclands have been famous in the careers that they have adopted, Sir Henry Acland's own generation and the generation junior to him supplying several examples.

Sir Henry Acland was educated at Harrow and Christ Church, Oxford His career at Harrow was, albeit marred by somewhat poor health, signalised by several minor successes. After a few terms at Christ Church his health compelled him to take a long holiday, and a tour in the Mediterranean seemed the most beneficial to a young man in his state of health; added to this he had all a young classical scholar's ardour to visit the scenes of which he had read so much. He therefore visited the eastern shores of the Levant and set himself the task of thoroughly mapping out the site of the ancient city of Pergamos The banks of the Simois and Scamander he explored with all the enthusiasm of a young and ambitious scholar and with care and much accurate observation made out a plan of the site of Priam's capital This work, together with a descriptive treatise, was published at Oxford in 1839. His panoramic plan of the Plains of Troy was very highly spoken of by the more erudite journals of the day, and is still frequently consulted by classical students. This tour, a combination of labour and pleasure, being completed, he returned to Christ Church and completed his University career by taking his Bachelor's degree in 1840. Having satisfied the authorities, according to the statutes, that he was *bene natus, bene vestitus, et mediocriter doctus* he was elected a Fellow of All Souls. The leisure that this appointment gave him also gave him the opportunity for devoting time to the science towards which he had always leaned, that of medicine. He proceeded to St. George's Hospital, the medical school of which institution was then adorned by Sir Benjamin Brodie, and there received, as well as the ordinary instruction given to a medical student, special tuition from Mr. Bullock, Mr. Squire, and Professor Quekett, the microscopist. During his residence in London he felt most keenly the difficulties and responsibilities of a student's life and being perhaps somewhat over-conscientious in details felt them all the more keenly. This caused him to direct his attention more especially to the general progress and status of the medical student. In 1843, being apparently tired of the then somewhat unsatisfactory life and bearing of the London student, Acland proceeded to Edinburgh, where he studied for a year or two under Dr. Alison, with whom he resided during that period In 1844 he gained a gold medal for an essay on "Feigned Insanity," the theme having been set for a class prize in medical jurisprudence. The essay, when it was published later, received a considerable meed of favour in the profession as a thoroughly capable treatise on a little known and most complicated subject. The work was not published at once, but a small number of copies were printed for private circulation.

In 1846 he graduated in medicine in the University of Oxford, and having in the same year become a Licentiate of the Royal College of Physicians of London he devoted himself with characteristic thoroughness to the duties attached to the post of Lee's Readership in Anatomy to which in 1845 he had been appointed. Without delay he commenced the formation of the extensive collection of physiological specimens, in Lee's Anatomical School at Christ Church, but since removed to the Oxford Museum. To this collection he devoted much hard work and it was not until 1853 that he had sufficiently collated the materials contained in this accumulation of excellent examples to publish a synopsis In 1847 he was appointed physician to the Radcliffe Infirmary, Oxford, a post which he held for nearly 40 years and at which institution some of his most notable work was It is seldom that a physician is elected a Fellow of the Royal Society at so early an age as 32 years, but in 1847 Acland obtained that honour, and was in the same year made local secretary to the British Association when it met for the second time at Oxford. His work in this capacity was marked by a thoroughness and an attention to detail which through life were Sir Henry Acland's marked qualifications.

Sir Henry Acland was always an earnest advocate of the claims of natural science as not only an item, but an essential feature, in the education of the young, and as early as 1848 he drew the attention of his university to what he considered rightly to be its duty—namely, the introduction of elementary science, physics, and the general ideas of chemistry and mechanics, as part of the *necessary course* in proceeding to the degree of Bachelor of Arts. His belief was that the study of the chief laws of the natural world was the most excellent channel through which the training and discipline of the human mind could be conducted, and he likewise urged that the study of the natural sciences, even in their most elementary branches, formed the very best possible mental discipline in the acquirement of true scholarship. These views were expressed by him in a most cogent manner, and so great was his influence on the conduct of study at his *alma mater* that he earned for himself the praise of Dr. Pusey, who described him as one who had devoted the prime of his life to the revival of the study of the Book of God's works. Acland's motive throughout this busy portion of his career may be briefly summarised in his own words: "To point out that the student of anatomy and physiology should make it his object to acquire above all things a knowledge of the changes, and of the causes and purposes of the changes which matter undergoes in its passage through living bodies." In this task the searcher after knowledge must trace the elements of the atmosphere and earth from their inorganic condition into those states which are capable of exhibiting the phenomena of life, and must ascertain in what order the ascent is made from the lowest living organisms to the highest and most complex. Proceeding from this basis the student must attempt to grasp the formation, nourishment, and changes of the living being itself, the forces which are engaged in maintaining the continuance of life, by what steps death is brought about, and at last the final return of the organic combinations of the inorganic elementary bodies to their former state. The idea of a "cosmos," an ordered state of all natural objects, was Acland's prevailing belief, and in the exposition of this theme he had the warmest and most enthusiastic support of his deeply attached friend John Ruskin.[1] As President of the Ashmolean Society Acland did much to popularise science in the University; and although there was during most of his long academic career at Oxford a lingering suspicion of all things scientific among certain of the guiding spirits of the oldest and most conservative educational body in England he lived to see this suspicion modified almost to the point of disappearance. In 1850 he became a *Fellow of the Royal College of* Physicians of London and in 1865 delivered the Harveian Oration before that body, which was afterwards published with a graceful dedication to Sir Thomas Watson, the President of the College, of whose talents and personality Acland was a sincere admirer.

In 1854 the cholera visited Oxford and the sanitary regulations of the city were placed almost entirely in the hands of Acland. Little was known of the etiology and pathology of cholera at this period, and it fell to Acland's lot to do more towards the proper understanding of the treatment and prevention of this scourge than any previous physician had done. "Many of the people of England," said he, "have yet to wake as from a dream. Though scientific men, aided by the press, have for many years striven to rouse us to a sense of insecurity, the habits of our country, the lengthy labour of discussion which is to be gone through in most public questions, and the precarious results of the votes of public assemblies, retard improvement and too often insure mischief. From this and other causes [illegible]

closest kind. From this time onwards the name of Acland was *intimately connected with all subjects of sanitation*, and more especially with the water-supply and sewage disposal of the Upper Thames valley; and in his capacity of a great sanitarian he published some valuable monographs on sewage and was one of the chief witnesses before the Select Committee appointed to inquire into the sewage of the metropolis. In 1869 he was appointed a member of the commission to inquire into the sanitary laws in England and Wales and his share in the work of that valuable body was almost preponderant, and in 1875 he was again a commissioner upon a Government inquiry in relation to sewage matters.

In 1851, on the death of Dr. Kidd, Dr. Henry Acland became Radcliffe librarian to the University and 11 years later it was by his exertions that the medical and surgical works at the Radcliffe Library were removed to their present and more appropriate quarters in the University museum. As Lee's Reader in Anatomy at Christ Church he lectured for 12 years, and when the death of Dr. Ogle, the Regius Professor of Medicine in the University, in 1857 rendered that position vacant, Dr. Acland was offered and accepted that distinguished office. His position was now such as to enable him to apply himself to the formation of the pathological collection of the museum, in which task he was greatly aided by the purchase at his instigation of the private pathological collection of Van der Kolk. To the Oxford Museum, in fact, he stood in much the same relation as did Sir Richard Owen towards the *Hunterian Museum of the Royal College of* Surgeons of England. The task of revivifying interest in scientific matters among the fellows of colleges was a much harder one than we can at this date conceive.

Sir Henry Acland's connexion with the General Medical Council was coeval with the founding of that body—namely, in 1858, when he was elected the Representative of the University of Oxford. In 1874 he became President of the Council, which dignity he supported with much distinction until 1887 when Sir Richard Quain was elected to the chair. His work on the Council was invaluable, and as he was likewise a member of the Medical Education Committee of the Hebdomadal Council of the University his influence on the shaping and direction of the course of studies of a medical student was very great indeed, and was invariably directed towards the enlargement of the scope of scientific training. To the production of the Pharmacopœia he contributed much valuable assistance, and throughout his connexion with the General Medical Council he devoted great energies to the advancement of the popular esteem in which members of his profession should be held. He took a very wide view of his duties and responsibilities as President of the General Medical Council. Not only did he use his influence for the good of the medical profession in his own country, but he extended his interests to foreign countries and in 1879 sent an eloquent and *encouraging letter to the authorities of the* Johns Hopkins University, urging his readers to higher things and to the raising of the standard of medical education. He always placed the greatest stress upon general culture as a necessary qualification for the successful medical man, and being himself of very wide interests and a thorough man of science, displayed in himself an example of the scholarly physician the parallel of which is not often seen. His great desire was to show students the way to learn and the way to express and make use of their learning in a thoroughly manly and useful manner. With regard to the fitness of women for the medical profession Sir Henry Acland held very decided views at a time when other medical men of almost or quite equal experience with him in matters of medical education were very doubtful. He stated his belief both that women could master the hard work necessary to fit them for this arduous calling and that when their studies had been completed they had every requisite gift for successful practice. He especially recommended the *female medical practitioner* as of incalculable service in India.

Acland's connexion with the Royal Family was long and intimate and commenced by his being appointed a member of the suite of His Royal Highness the Prince of Wales when he paid his visit to Canada and the United

---

ood of seeing a noble young
ur, reckless daring, and happy
y through all, like a girl's in
e he could pull me on, being
years ahead of me, yet glad of my

States in 1860. On returning to Oxford he was appointed honorary physician to His Royal Highness who entered the University in that year. In the same year he received the honorary degree of LL.D. from the University of Cambridge and was made an honorary student of Christ Church. In 1867 Dr. Acland was appointed by Government a member of the Cubic Space Committee, the reference of which was the state of the metropolitan workhouses as regards the space and area required for each pauper in the dormitories and in the wards of infirmaries.

Sir Henry Acland's literary works are both numerous and inclusive of a remarkable range of subjects, embracing not only themes intimately allied to medicine and pathology but several valuable contributions to general literature. To his first work on the "Plains of Troy," published in 1839, we have alluded above and among his other works perhaps the most notable is the useful volume on "National Health" written in 1871 at the desire of the President and Council of the Royal College of Surgeons of England. This work deals exhaustively with the essentials of public health as then understood with regard to environment, food, and water. "Village Health and Village Life" was written in 1884 for the International Health Exhibition and is characterised, as indeed are all his writings, by an ease and elegance of diction attained to only by a finished scholar. His Harveian Oration in 1865 was a very notable piece of philosophical work. It was the first of these orations delivered in English and indeed no fitter man than Acland could have been found to demonstrate that dignity and eloquence can be every whit as well blended through the medium of the English tongue as through that of the more sonorous Latin. He reviewed the opinions of the various philosophers who have discussed with greater or less exactness the doctrine of final causes and made an able refutation of Comte's arguments against design. His position was briefly and eloquently summed up in the following words: "No student of nature worthy of the name looks on the problem of this world as other than vast and inexplicable. He pretends no more than to see as by an image, darkly, and to bend before the Cause of all." Of his beautiful work on the "Oxford Museum," which he wrote in collaboration with his friend John Ruskin, several editions have appeared between the date of its first appearance in 1859 and 1893, when it was considerably enlarged and produced in sumptuous form with admirable illustrations. The last edition includes a photograph by Miss Acland of Sir Henry Acland and Ruskin taken in the garden at Brantwood in August, 1893. The two friends are seated in garden-chairs and are represented as in close commune over a book of prints or plans. Another of his works which calls for attention is his graceful and appreciative biography of his old friend and master, Sir Benjamin Brodie.

Sir Henry Acland was one of the few members of our profession not connected with the naval or military services who have received the honour of a Companionship of the Bath. To this honour he was admitted in 1883 in recognition of his services to the profession and to the cause of medicine and public health, and in the following year he was raised to the rank of Knight Companion of the Order. In 1890 he received the honour of a baronetcy of the United Kingdom, and it was acknowledged on all sides that few men had greater claims to the distinction either in the University of Oxford or in the medical calling at large. Among the numerous honours enjoyed by Sir Henry Acland were the Doctor of Laws degree of Cambridge and of Dublin, the degree of Doctor of Civil Law of the University of Durham, and likewise the titles of Doctor of Medicine of Trinity College, Dublin, Fellow of the Royal Society, member of the medical and philosophical societies of Philadelphia, Christiania, Athens, New York, and Massachusetts, and of an almost countless array of medical and scientific societies throughout England, Europe, and America. He was a Knight of the Rose of Brazil, which order was conferred on him in recognition of his great services to science in the matter of the cholera investigations to which we have before alluded.

Sir Henry Acland's stately and venerable figure will be greatly missed in the streets and quadrangles of Oxford, where he was deservedly one of the best known and most highly respected personages of the University, and beyond the respect in which all who had the honour of his acquaintance held him he was deeply beloved by many who owe much to his kindly sympathy and genial encouragement. Many generations of medical graduates of the University will remember his uniform courtesy to them and his power of setting at their ease young and undistinguished members of the University with whom he was brought in contact. On the morning of a degree day he was in the habit of asking those whom he was about to present for a degree in medicine to breakfast with him at his delightful old house in Broad-street. Before breakfast prayers were read by him, the book used being solemnly brought in upon a flat fire stained stone. (This stone, by the way, was dug up during some excavations in Broad-street necessitated by the erection of the new front of Balliol College and was supposed to have been one of the stones surrounding the stake at which Ridley and Latimer suffered the penalty of burning.) Breakfast followed, a meal hardly to be forgotten by his guests for the varied and interesting talk of the host. It was on this and similar occasions that he showed himself a type of a fashion of man now almost completely passed away. 'Courtesy and scholarship still abound, but the old-world setting of these virtues, so beautifully indicated in Ruskin's tribute to his friend,' has somewhat ceased to be. In 1846 he married Sarah, daughter of the late William Cotton, F.R.S., a philanthropist who devoted so much of his wealth and energies to the advancement of the cause of the Church of England in the East End of London. This lady, who died in 1878, brought her husband a family of six sons and one daughter. Sir Henry Acland is succeeded in the baronetcy by his son, Rear-Admiral William Alison Dyke Acland, R.N., a naval aide-de-camp to Her Majesty the Queen. One son—viz., Dr. Theodore Dyke Acland—follows his father's profession of medicine.

SAMUEL HENRY SWAYNE, M.R.C.S. ENG., L.S.A.

MR. SAMUEL HENRY SWAYNE, who died at his residence in Pembroke-road, Clifton, on Oct. 12th, in his eightieth year, was a member of an old Gloucestershire family, his grandfather being vicar of Pucklechurch and his father having practised as a surgeon in Bristol. Mr. Swayne received his medical education at the Bristol Medical School and St. Bartholomew's Hospital and qualified as M.R.C.S. Eng., and L.S.A. in 1843 and 1844 respectively. Shortly afterwards he commenced practice in Clifton, and he continued to follow his professional duties until three months ago, when he was laid aside by cardiac trouble. Mr. Swayne was delicate from childhood and was always obliged to take care of his health. He was an ex-president of the Bristol Medico Chirurgical Society, and the Bristol Naturalists' Society, a vice-president of the Bristol and Gloucester Archæological Society, and honorary secretary of the Bristol Museum. He took a great interest in Church matters and was associated with his brother, Dr. Joseph Griffiths Swayne, in the building of All Saints' Church, Clifton. Mr. Swayne lost his wife 30 years ago and leaves no children. He is survived by three of his brothers, one of whom, Dr. J. G. Swayne, is the consulting obstetric physician to the Bristol General Hospital.

RICHARD HAMILTON COWAN, M.R.C.S. ENG., L.S.A.

THE medical profession in Wigan has received a severe blow through the unexpected death of Mr. Cowan which took place on Oct. 6th after a very short illness. Mr. Cowan, who was only 42 years of age, was apparently in his usual health on Oct. 2nd, but on the following morning he was seized with a rigor; he nevertheless went to the house of a midwifery patient who had sent for him, but was soon compelled to hand over the case to a brother-practitioner and to return home to bed. Symptoms of pneumonia were then recognised by his medical friends who were called in, but all their endeavours to check the progress of the disease were unfortunately unavailing. The deceased was the son of Mr. Richard Hamilton Cowan, R.N., of Southsea. He entered as a student at the London Hospital in 1877 and in 1881 he became qualified as M.R.C.S. Eng. and L.S.A., after which he held the position of assistant medical officer in Birmingham Workhouse Infirmary, and in 1883 he went to Wigan. Two years later he entered into partnership with Mr. C. D. Shepherd of that town, and in 1897 he succeeded to the whole of the practice. Kind, genial, and sympathetic, he was beloved by his patients and held in the greatest esteem by his colleagues. In 1892 he was elected an honorary medical officer of the Royal Albert Edward Infirmary and devoted his energies to the [illegible]; he was particularly [illegible] was very successful [illegible] time of his death he was president of the Wigan Medical Society and had formerly been president of the local chess club Mr. Cowan has left a widow and three children. The funeral took place at Standish on Oct. 10th and was largely attended, the infirmary board of management and several public bodies being represented

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Max Schaeffer, a well-known Bremen laryngologist, at the age of 55 years by an Alpine accident.—Dr. Abraham Kuhn, Professor of Otology in the University of Strasburg, at the age of 62 years. He was a very skilful operator and had published numerous researches on the comparative anatomy of the ear.—Dr. Alex. Zarewicz, Lecturer on Skin Diseases in the University of Cracow.—Dr. Jacob M Da Costa, a well-known Philadelphia physician.—Dr. A. W Griggs, formerly Professor of Medicine at the Atla [illegible] T Albert, Professor of Clinical [illegible] Rudolf Arndt, Extraordinary Pr[illegible] and Director of the University [illegible] age of 55 years. He published a text-book and many monographs on psychiatric subjects. Recently he wrote some papers of a philosophical and biological character taking up a somewhat peculiar position.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6578 births and 3799 deaths were registered during the week ending Oct. 13th. The annual rate of mortality in these towns, which had been 18·5 and 17·8 per 1000 in the two preceding weeks, further declined last week to 17·1. In London the death-rate was 14·8 per 1000, while it averaged 18·5 in the 32 provincial towns. The lowest death-rates in these towns were 10·5 in Cardiff, 11·9 in Croydon, 12·6 in West Ham and in Leicester, and 13·0 in Bolton; the highest rates were 23·1 in Liverpool, 23·8 in Gateshead, and 24·8 in Manchester and in Salford The 3799 deaths in these towns included 563 which were referred to the principal zymotic diseases, against 776 and 673 in the two preceding weeks; of these 289 resulted from diarrhœa, 85 from diphtheria, 64 from "fever" (principally enteric), 59 from whooping-cough, 39 from measles, and 27 from scarlet fever The lowest death-rates last week from these diseases occurred in Cardiff, Halifax Bradford, and Newcastle; and the highest rates in Wolverhampton, Leicester, Salford, and Gateshead. The greatest mortality from measles occurred in Swansea; from whooping-cough in Derby and Gateshead; from "fever" in Plymouth, Wolverhampton, and Sunderland; and from diarrhœa in Wolverhampton, Manchester, Burnley, and Gateshead. The mortality from scarlet fever showed no marked [illegible] in any of the large towns The 85 deaths from dipt[illegible] included 26 in London, 11 in Leicester, seven in [illegible] and seven in West Ham No fatal case of small-pox was registered last week in any of the 33 large towns; and only one small-pox patient was under treatment in the Metropolitan Asylums Hospitals on Saturday last, Oct. 13th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2187, against numbers increasing from 1703 to 2071 on the six preceding Saturdays; 322 new cases were admitted during the week, against 269, 318, and 313 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had declined from 203 to 164 in the three preceding weeks, rose again last week to 173, but were 74 below the corrected average The causes of 33, or 0·9 per cent, of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Leeds, Hull, Newcastle, and 13 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, and Manchester.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·9 and 19·3 per 1000 in the two preceding weeks, declined again to 18·0 during the week ending Oct. 13th, and was 0·2 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14·5 in Edinburgh and 14·6 in Leith to 19·7 in Aberdeen and 21·1 in Dundee. Th[illegible] towns included 36 which were [illegible] whooping cough, seven to scarle[illegible] five to "fever" (including one [illegible] to measles, and two to small-pox In all, 74 deaths resulted from these principal zymotic diseases, against 91 and 107 in the two preceding weeks. These 74 deaths were equal to an annual rate of 2·4 per 1000, which was 0·1 per 1000 below the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had been 49 and 52 in the two preceding weeks, declined again last week to 36, of which 17 occurred in G[illegible] four in Paisley, and three in L[illegible] [illegible]ooping-cough, which had been 12 and 18 in the two preceding weeks, declined again to 13 last week, and included 10 in Glasgow and two in Greenock. The fatal cases of diphtheria, which had declined from 11 to five in the three preceding weeks, rose again last week to seven, of which four were registered in Glasgow and two in Dundee. The seven deaths from scarlet fever corresponded with the number in the preceding week, and included five in Glasgow. The deaths referred to different forms of "fever," which had increased from four to 13 in the five preceding weeks, declined again last week to five and were all recorded in Glasgow, where the two fatal cases of small pox were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 101, 100, and 98 in the three preceding weeks, rose again last week to 104, and were slightly above the number in the corresponding period of last year. The causes of 22, or nearly 4 per cent, of the deaths in these eight towns last week were not certified

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·5 and 26·0 per 1000 in the two preceding weeks, further rose to 26·4 during the week ending Oct. 13th. During the past four weeks the death-rate in the city has averaged 25·4 per 1000, the rate during the same period being 16·0 in London and 17·6 in Edinburgh The 177 deaths belonging to Dublin registered last week were three in excess of the number in the preceding week, and included 21 which were referred to the principal zymotic diseases, against 25 and 36 in the two preceding weeks; of these 15 resulted from diarrhœa, four from "fever," one from whooping-cough, and one from diphtheria. These 21 deaths were equal to an annual rate of 3·1 per 1000, the zymotic death-rate during the same period being 1·9 in London and 1·0 in Edinburgh The fatal cases of diarrhœa, which had 18 and 27 [illegible] again last week to 15. [illegible] of "fever," which had [illegible] ceding weeks, rose a[illegible] which had been three, three, and [illegible]ng weeks, declined again last week [illegible] in Dublin last week included 45 of infants under one year of age and 41 of persons aged upwards of 60 years; the deaths of infants showed a marked decline while those of elderly persons exceeded the number in the preceding week Seven inquest cases and five deaths from violence were registered, and 56, or nearly one-third, of the deaths occurred in public institutions. The causes of 17, or nearly 10 per cent., of the deaths in the city last week were not certified

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

INSPECTOR-GENERAL of Hospitals and Fleets H. C Woods, M.V.O., is appointed to the *Victoria and Albert*, reappointed on promotion.

The following appointments are notified:—Surgeons: R. L Dickinson to the *Hussar* and W. P. Walker to the *Majestic*.

ROYAL ARMY MEDICAL CORPS.

Captain Watson is granted the temporary rank of Major whilst employed in South Africa. Temporary Captain J. K. Butter resigns his commission.

Surgeon-Major D. Elcum, I.M.S., retired, has been appointed for duty in the Home District. Lieutenant G. Baillie arrived at Chatham on Oct. 4th for duty. Lieutenant B. B. Burke arrived at Colchester on Oct. 3rd for duty. Lieutenant L L. G. Thorpe arrived at Dover for duty on Oct. 3rd, and has been posted to the Station Hospital, Western Heights. Lieutenant-Colonel R. Blood officiates as District Principal Medical Officer, Bombay Command, pending the appointment of a successor to Colonel Maunsell, retired.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain J. K. Butter resigns his commission.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the South Staffordshire Regiment: Surgeon-Captain J. K. Butter resigns his commission. 1st (Pembrokeshire) Volunteer Battalion the Welsh Regiment: Horace Lake Lowis to be Surgeon-Lieutenant. 2nd Volunteer Battalion the York and Lancaster Regiment: Surgeon-Lieutenant H. H. B. Wilkinson retires under paragraph 111 Volunteer Regulations, and is granted the rank of Surgeon-Captain, with permission to wear the uniform of the battalion on retirement.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Lieutenant-Colonel R. N. Campbell, I.M.S., Civil Surgeon, on return from furlough, are replaced at the disposal of the Government of India in the Home Department. Lieutenant-Colonel J. W. U. Macnamara, I.M.S., Civil Surgeon, on return from furlough, is posted to Tezpur and appointed to hold civil medical charge of the Darrang district. Captain A. Leventon, Officiating Civil Surgeon, Darrang, on being relieved by Lieutenant-Colonel J. W. U. Macnamara, is transferred to Sibsager and appointed to hold civil medical charge of that district until further orders. Major E. R. W. C. Carroll, I.M.S., Civil Surgeon, on return from furlough, is posted to Dhubri, and appointed to hold civil medical charge of the Goalpara district. Major E. C. Hare, I.M.S., Civil Surgeon, on return from furlough, is posted to Gauhati and appointed to hold civil medical charge of the Kamrup district. Captain H. C. French, R.A.M.C., has been transferred from the Mhow district to the Nagpore district, and Captain W. Tibbits, R.A.M.C., from the Nagpore district to the Mhow district.

TRANSVAAL WAR NOTES.

Most of the members of the Scottish National Hospital have arrived in England.

Professor Alfred W. Hughes, Mr. J. Lynn Thomas, Dr. E. Laming Evans, and Mr. Mills-Roberts of the Welsh Hospital are returning to England in the *Saxon*. They are expected to arrive at the end of the present week. Before their departure from Pretoria Surgeon-General W. D. Wilson, principal medical officer of the Army in South Africa, wrote to Professor Hughes as follows: "I must now thank you and your staff for your great help. You have worked loyally with us, and I believe all the Royal Army Medical Corps in South Africa have a warm place in their hearts for you, and they fully appreciate the cordial assistance you have given us." The nurses and orderlies are still at Pretoria.

Captain F. J. Wade-Brown, R.A.M.C., and Civil Surgeon C. R. Martin have been discharged from hospital for duty.

THE WAR IN CHINA.

It is quite clear that the international forces in China have an uncommonly troublesome task before them. This does not arise so much from any difficulty in overcoming the forces opposed to them, although these must be considerable where there are any number of Chinese to take the place of those slain or defeated in battle, and where human life is held to be of little value, as from the fact that military success makes no impression upon the Imperial Court and those in authority in China, located as they are in distant and inaccessible positions. It is like the case of the Irish landlord who said that if his tenantry thought to intimidate *him* by murdering his agents they were much mistaken. The Chinese puzzle consists in the fact that there is no constituted authority to dictate terms to and no reliance to be placed upon Chinese decrees and orders which are probably wholly insincere and only issued to gain time. Meanwhile the British contingent sent from India has already done excellent service. It is apparently amply supplied by the Government of India with hospitals and hospital ships and medical stores. The Maharajah Scindia has been most patriotic and generous in providing at his own expense a splendid hospital ship for the expedition. It is reported that dysentery has been very prevalent of late among the troops at, and in the vicinity of, Tien-Tsin.

WEST AFRICAN FRONTIER FORCE.

In THE LANCET of March 31st, 1900 (p. 952) some account was given of the general medical history of this force up to March 31st, 1899. A report on the health of the British troops serving with this force for the year ending Dec. 31st, 1899, has been drawn up by Mr. D. K. McDowell, the acting principal medical officer, and has been recently published by the Colonial Office. The statistical summary with which the report closes is as follows: "Average annual strength, 151; percentage of admissions, 326·5; average daily sick, 6·22; admissions for fever, 377; average duration of fever, 5·58 days; percentage of deaths from fever, 5·3; percentage of deaths from all diseases, 9·2." The 377 admissions for fever just mentioned consisted of 354 cases of malarial fever (with five deaths), and 23 cases of blackwater fever (with three deaths). The total deaths during the year were 14, consisting of the eight just mentioned, and in addition one each from dysentery, heat apoplexy, heatstroke, enteritis, ptomaine poisoning, and abscess of the liver. 37 men were invalided to England. The general health of the force was therefore anything but good.

THE ASHANTI RISING.

Good progress is being made in the war on the west coast of Africa in suppressing the rising of the Ashantis and other turbulent tribes. It is generally believed that notwithstanding the anticipation of some further fighting on the part of some of them the majority of those opposed to us will soon surrender. Major Holford's column which left Kumasi to open communication with Kintampo has returned. The column suffered severely during the rains and the health of the troops was unsatisfactory owing to their hard and fatiguing work and exposure. Although there is a good deal of the usual diseases incidental to field service in such a climate at this season, still the amount of sickness has not been anything like what it would have been among European troops under similar circumstances.

THE NAVAL VICTUALLING COMMITTEE.

The Admiralty Victualling Committee, which has been sitting at Devonport during the past week under the presidency of Vice-Admiral Rice, has now gone to Portsmouth to continue its inquiries. At Devonport several officers and men were examined, and in addition to making inquiries with the object of improving the victualling of the navy the committee are collecting information and suggestions with a view to the adoption of a reform in canteens on Her Majesty's ships. The committee consists of six members, including Deputy Inspector-General of Hospitals G. J. Irvine.

ORDER OF THE BRILLIANT STAR OF ZANZIBAR.

The Queen has given to Captain Patrick Percy Kilkelly, I.M.S., Her Majesty's Royal licence and authority to accept and wear the Insignia of the Fourth Class of the Order of the Brilliant Star of Zanzibar, conferred upon him by His Highness the Sultan of Zanzibar.

LEAN'S ROYAL NAVY LIST.

The ninety-second quarterly issue of this most useful compilation, now in its twenty-third year, has just been published by Messrs. Witherby and Co., 326, High Holborn, and 4, Newman's-court, Cornhill. No better arranged reference book to the Royal Navy could be desired.

A correspondent of the *Army and Navy Gazette* writes from South Africa:—"The foreign attachés when they came back to Cape Town were loud in praise of Lord Roberts and his methods, and on leaving the Cape united in drawing up an address expressing cordial gratitude to his lordship for his proverbial courtesy. Every attaché signed his name and added an expression of appreciation of the consideration he had received. As one of the officers remarked to me: 'It has been a revelation to see on all hands so much kindly feeling—not forced, but real thoughtfulness and soldierly generosity. I do not exaggerate in the least; I mean what I say. We have been made very

good-tempered and
iomies your soldiers

. N., invalided from
miah Sugrue, R N.,
station, landed at
Plymouth on Oct. 6th.

Lieutenant-Colonel P. F. O'Connor, I.M.S., has been appointed principal medical officer to the troops at Shanghai.

Correspondence.

"Audi alteram partem."

MEDICAL SERVICE IN THE HIGHLANDS AND ISLANDS OF SCOTLAND.

To the Editors of THE LANCET.

SIRS,—To meet the undoubted hardships of certain Poor-law medical officers in Scotland, the first remedy is to put the Scottish Poor-law Medical Grant on the same footing as it stands in England and Ireland—that is, that Scotland should get one-half of the actual expenditure instead of a fixed contribution which is less than that moiety. The second, that the Poor-law medical officers should not be dismissed unless with the sanction of the Local Government Board for Scotland. The third, that manses for the doctors should be provided in the remote districts of the Highlands and islands. The fourth, that they should have the right to be superannuated on a fair scale, founded on proper principles. The fifth, that they be entitled to an annual holiday, the parish council giving a fair allowance for providing a substitute.

The first of these points is really a ratepayers' question, and there can only be one answer if Scotland is to get equal justice when compared with other parts of the United Kingdom. Against the second proposal there are certain objections which are more or less valid, and it would be very difficult, unless the Government take full charge of a Bill to alter the present status of the medical officers, to get it passed, seeing that most of the parish councils would naturally be opposed to any such restriction. If this be so, then some other method must be thought of. The hardship scarcely applies in any cases except in those where the subsidy is really given not merely for attendance on paupers but as a guarantee for securing the services of the local doctor. The result of this arrangement is that if the doctor loses his parochial appointment he is really deprived of his means of living and must abandon the struggle

Seeing that the public at large really helps to pay for medical attendance to all and sundry in these parishes, it ought in all fairness to have its say, both in making and unmaking such appointments A precedent is fortunately at hand in the case of the schools in certain island parishes where, in the case of extraordinary grants, H.M. inspector of schools acquires a right to sit at the school board. If the

ad the same right, then
was done to the parish
doctor, and would likewise take care that only competent men were appointed and that proved incompetent men were dismissed.

With regard to the third point, all that is wanted is that permissive power be given the parish councils for such purposes to borrow money to be repaid on the same terms as similar loans granted to local authorities. It is not necessary to argue in favour of some form of superannuation, or as to giving permissive powers to parish councils to grant holidays to their medical officers. Seeing that these are already given in Ireland, surely Scotch Poor-law medical officers are entitled to the same privilege, a privilege which on every ground is likely to be for the good, not only of the doctor, but also of his patients

I am, Sirs, yours faithfully,

WILLIAM BRUCE, M D. King's Coll., Aberd.,
Direct Representative for Scotland on the General Medical Council.

Oct 16th.

A SUGGESTION FOR THE EXTERMINATION OF THE MOSQUITO FROM COLONIAL HOSPITALS AND DWELLINGS.

To the Editors of THE LANCET.

SIRS,—It behoves all who are interested in the relation of the mosquito to malaria to offer any suggestion which may be of service to the residents in malaria-stricken districts. I have no personal knowledge of the mosquito or his habitat, but I should like to tell a story which in the hands of those acquainted with both may perchance prove of value. As I have always four or five horses in my stables I built a large corn-loft, on the most approved principles to keep out vermin, to enable me to buy in the cheapest market by purchasing 50 quarters of oats at a time. Many years ago I found my horses were not up to the mark, and on inquiry ascertained that they refused their corn. I immediately went into my corn-loft and discovered that many bushels of oats were simply husks, the corn having been consumed by the ravages of moths. This was such a new experience to me that it required some consideration to cope with it in the future. As the mischief was all done for that season I removed the destroyed corn, and when the remainder was consumed I had the walls and ceiling washed with fresh slaked lime, so that it was put on hot, into which was stirred sufficient sulphur to make it somewhat yellow. This is renewed every few years and causes no unpleasant smell. But into the precincts of my corn-loft no moth or fly ever dares to enter. Would this plan similarly affect the mosquito is the suggestion I would offer for what it is worth?

I am, Sirs, your obedient servant,

Rugby, Oct 15th, 1900. CLEMENT DUKES.

THE INCUBATION PERIOD OF MALARIA.

To the Editors of THE LANCET.

SIRS —The following case may be of value in settling the incubation period of malaria.

A man, aged 32 years, left Grandola in Spain on July 25th, 1900, in the afternoon. He arrived at Alcacer do Sal at 8 o'clock in the evening and left again on the top of a diligence for Poicerão at 10 30, which he reached at 4 A.M. to catch the 4 20 train. Alcacer do Sal has a very bad reputation for malaria; it is a salt swamp and mosquitoes abound. From 8 P M. on July 25th to 4 20 A M. on July 26th my patient was badly bitten by mosquitoes, and this is the only occasion on which he has been in a malarious district. On arriving at Southampton about 10 P M. on August 12th he did not feel very well; he remained on the boat and left by the morning train for London on August 13th. About 4 P.M. that afternoon he began to feel very ill and could hardly walk and at 8 o'clock, while trying to have some dinner, a definite attack came on. This was at once recognised by a friend who had been many years in China as ague. The patient had a very bad night but was comparatively well next day. A second attack came on about 8 o'clock on August 16th and as my patient became slightly delirious and was very feverish a medical man was hastily summoned. The blood was unfortunately not examined and the patient since then has had several much milder but irregular attacks. The incubation period, therefore, in this instance seems to have been 18 days—from the night of July 25th-26th to the evening of August 13th

I am, Sirs, yours faithfully,

W FRANK COLCLOUGH,
Medical Officer to the British Hospital, Oporto

Oporto, Portugal, Oct 9th, 1900

THE ORANGE RIVER COLONY AS A HEALTH RESORT.

To the Editors of THE LANCET.

SIRS,—Now that winter is approaching and the profession and public alike are once more turning their attention to South Africa as a health resort, I venture to opine that first-hand information from those who have been there may not be unacceptable to those who propose to go. My own experience is limited to the Harrismith district of what was the Orange Free State, about which I will say no more than that it is second to none in point of suitability for cases of threatened or early tuberculosis. My object in writing is not to advocate this above any other locality, but to make known the existence, about 10 miles from the town of Harrismith, of what is a considerable rarity upon the high veldt—a large and comfortable farmhouse where paying guests are welcome. Of this house and its hospitality I had in the early part of last year two months' personal and happy experience; and I have lately heard that the host and his wife, both loyal English Afrikanders, have survived the dangers and hardships of the war and are once more in a position to do their best for a limited number of visitors. It would give me pleasure to impart to anyone, medical or lay, all that I know about this house and its surroundings.

I am, Sirs, yours faithfully,
W. LEE DICKINSON.

9, Chesterfield-street, Mayfair, W., Oct. 12th, 1900.

THE CAUSATION OF SCURVY.

To the Editors of THE LANCET.

SIRS,—Being much interested in scurvy I read with great expectation the article by Dr. Vaughan Harley and Mr. F. G. Jackson in THE LANCET of April 28th, 1900, p. 1184, and that by Staff Surgeon W. E. Home, R.N., in THE LANCET of August 4th, p. 321, and I regret to say that I am disappointed, for the following reasons.

Dr. Harley, as the result of feeding monkeys with bad meat, came to the conclusion that scurvy is caused by some poison in tainted (flesh) food. Now this may or may not be correct, but it quite fails to account for the disease in men who only eat good grain stuffs. I have seen a good deal of scurvy amongst non-meat-eating Indian troops both on service and in peace time, and have always found it to be caused solely by a diet containing too little fresh vegetables or fruits. I am of opinion that the disease was so caused as it was always cured by the addition to the diet of fresh potatoes, or dates, or limes, without any change being made in the food and water the patients were originally taking, without change of locality or circumstances, and without drugs. I am unable to give an opinion as to the prophylactic or curative powers of tinned milk, of pressed vegetables, of onions, of preserved limejuice, of fresh meat, or of fresh milk, though a recent experience of mine seemed to show that those men who could afford to buy milk were not attacked, while others under exactly the same conditions, but without milk, were attacked, and as regards fresh meat Nansen has proved that a diet of that alone is quite sufficient.

Staff-Surgeon Home suggests that scurvy is "an infection of the mouth with micro-organisms out of decayed food." I do not think that this is so, as in large outbreaks I have seen amongst non-meat-eating men, the various grains which formed the food staples were excellent, and the affection of the gums was not the first symptom observed. Also the gums are not in a state of inflammation—gingivitis. At a certain stage of the disease—generally early, very occasionally late, and I have read sometimes not at all—they become swelled by the scorbutic fibrinous infiltration (except places where teeth are absent), and any ulceration which may supervene later is quite unspecific. With reference to the "orthodox view" given by Staff Surgeon Home let me give a typical case. A healthy sepoy, living in cantonments, wishes to save money. He has to pay for and eat the flour, rice, or dhal cooked by his company cook, so he saves by depriving himself of extras such as milk and vegetables, and meat if a meat eater. In two or three months that man will be in hospital with scurvy, and in a fairly short time he will, by the simple addition of fresh limes or potatoes to his original diet, be quite fit for duty. "Preceding hardships" are not required for the production of scurvy, and I think it a good working rule to fear that men will become scorbutic if they cannot get either green vegetables, or fruit, or fresh milk, or fresh meat.

I am, Sirs, yours faithfully,
C. B. MAITLAND, F.R.C.P. Edin.,
Lieutenant Colonel I.M.S.

Grantown-on-Spey.

"TWO CASES OF ARTERIO-VENOUS ANEURYSM."

To the Editors of THE LANCET.

SIRS,—I am much interested in the two cases of arterio-venous aneurysm reported in THE LANCET of Oct. 13th, (p. 1073) by Lieutenant-Colonel J. T. Lewtas, I.M.S. The result of the first case, treated by ligature of the vein by means of two ligatures applied one above and one below the opening into it and by ligature of the artery above the opening into it, is eminently satisfactory, for the disease was cured and the limb was saved. The result of the second case is, I should consider, eminently unsatisfactory, for the limb was amputated. I have on one occasion tied the artery above the opening into it for the cure of arterio-venous aneurysm of the popliteal artery and vein with the same unfortunate result as that following Colonel Lewtas's operation and it is curious how frequently gangrene has followed this procedure. Gangrene is much more common in cases of femoral arterio venous aneurysm after ligature of the artery by a single ligature applied to the vessel above the opening into it than when a ligature is applied above the aneurysm for the cure of popliteal aneurysm (Hunter's operation). I do not know that this is to be wondered at, but it is certainly true. On the other hand, tying both artery and vein above and below the opening into them and dissecting out the sac has been attended by most satisfactory results. This is undoubtedly a severe and sometimes a difficult operation, but it can usually be performed. In one case reported by Dr. Keen where the common carotid and the jugular veins were involved it was found impossible to dissect out the sac, but even this case was cured.—I am, Sirs, yours faithfully,

FREDERICK PAGE,
Professor of Surgery, Durham University.

Newcastle-upon-Tyne, Oct. 15th, 1900.

"THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY AND THE GENERAL MEDICAL COUNCIL."

To the Editors of THE LANCET.

SIRS,—In reply to Mr. T. Bryant's letter, dated May 5th, published in THE LANCET of Oct. 13th (p. 1097), I beg leave to say that I still regard as accurate the statement contained in the second paragraph of that letter. The paragraph is printed between inverted commas and is quoted from the last annual report of my society. I know no reason why anyone should accept as convincing Mr. Bryant's expression of his personal opinion concerning the cases to which he refers; and I see nothing more in his letter than a mere expression of his personal opinion.

I am, Sirs, yours faithfully,
HUGH WOODS,
Honorary General Secretary.

Oct. 15th, 1900.

"THE SMOKE NUISANCE."

To the Editors of THE LANCET.

SIRS,—In answer to the letter from Mr. F. W. Alexander on the above subject which appeared in THE LANCET of Oct. 13th, (p. 1098) I should like to point out that the coal Smoke Abatement Society is well aware that it or any individual may prosecute in a case of smoke nuisance, but that having considered the matter in all its bearings the committee of the society has determined, at any rate for the present, not to institute proceedings itself. The principal difficulty in the society instituting proceedings is that the society would have to prove in court a nuisance by the smoke, a not always easy thing to prove to the satisfaction of a magistrate, whereas if the vestry prosecutes it only has to prove that black smoke was emitted, which under Section 23 and 24 constitutes a nuisance. Where there are public authorities constituted for the purpose of suppressing these nuisances my committee considered that it would be unwise of them to commence legal proceedings in cases which now number some thousands.—I am, Sirs, yours faithfully,

H. A. DES VŒUX.
Hon. Treasurer, Coal Smoke Abatement Society.

Oct. 17th, 1900.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Medical Staff for the China Expeditionary Force.—The Hospital Ship Gwalior.—Beri-beri on H.M.S. Sphinx.—The Pasteur Institute at Kasauli.—Further Increase of Plague in India.

ONE hundred and thirty medical officers (all but eight of whom belong to the Indian Medical Service) having been detailed for duty with the China Expeditionary Force there

has been a great strain on the medical service. Many [illegible] ment have found it necessary to engage the services of purely civilian and unofficial practitioners.

The hospital ship *Gwalior* which has been provided by the Maharajah Scindhia is to sail on Sept. 22nd. She is one of the boats of the British India line. Extensive and costly alterations have been made. She was first carefully surveyed in the dry dock and was then dressed in a coat of light-grey paint with red crosses on her bows, sides, stern, and funnel. She is now lighted throughout by electricity and she has electric fans. There will be separate accommodation for convalescents and a completely isolated infectious ward on the poop. A simple and efficacious method of taking the sick on board has been fitted by means of a large port in the ship's side with a conveyance by a light trolly to the beds. For fracture and certain surgical cases swinging beds have been provided. Electric stoves have been furnished and with these water can be boiled in a few minutes. The *Gwalior* has been fitted not only with all the necessary apparatus of ventilation for use in [illegible] China. The vessel is a three-masted steamer of 4200 tons register and she closely resembles the hospital ship *Carthage*. There will thus be, including the *Maine*, three vessels in Chinese waters, so that with the three base hospitals the sick and wounded should be well provided for. The expenses of the *Gwalior* will probably exceed £100,000 and she will have to be restored to her owners in her original condition.

Five cases of beri-beri have occurred amongst the bluejackets on board H.M.S. *Sphinx*, which left Muscat on Sept. 13th and arrived in Bombay on the 17th. The vessel has been placed in quarantine and has been thoroughly disinfected and the patients have been removed to hospital.

In consequence of the artificially-induced opposition to the Pasteur Institute at Kasauli it is advisable to record the success which has attended the institution since its opening on August 9th. There have now been 42 admissions, and 31 patients have completed the course of treatment. During the past week a British soldier and two native civilians were admitted, while four officers from Bombay, a British soldier, and two native civilians are on the way. The native patients include both Mohamedans and Hindoos, and all appear only too anxious to avail themselves of the treatment.

While plague is again on the increase the numbers under famine relief [illegible] al figures have decreased [illegible] week and at present there [illegible] on relief works and two and a half millions on gratuitous relief. This week's plague returns show a further increase, the total [illegible] en to 1136. Bombay city [illegible], Calcutta 81 (including [illegible] In the Mysore State the [illegible] now indications that the disease is again developing i[illegible] mortality (1084, equal to 66 44 [illegible] very high, but the recorded [illegible] increased. In Calcutta, altho[illegible] tinue much the same as for many weeks past, the general mortality is increasing. The districts of Poona, Nasik, Surat, Thana, and Belgaum give cause for great anxiety. Cholera is raging severely in Kashmir, especially in Srinagar and the surrounding districts. It has rapidly gone down in Bombay city and very few cases are now occurring in the army. The principles to be observed in connexion with plague [illegible] been finally settled by the [illegible] reigned in Bengal, so that it is not surprising to hear that the Lieutenant-Governor considers that the work of the Bengal Plague Commission is no longer necessary. The Local Commission has therefore been dissolved.

Sept. 20th.

BRISTOL EYE HOSPITAL.—The committee of the Bristol Eye Hospital have received £1263 as a result of the recent *fête* held at the Zoological Gardens, Clifton.

THE UNIVERSAL EXHIBITION OF PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

THE BELGIAN HYGIENE SECTION.

DRAWN away from the Exhibition by the long succession of International Congresses I feel, now that the eleventh hour is approaching, how little I have seen and described of this most marvellous accumulation of the world's wonders. Every visit means the discovery of something new, something which had been missed on a previous occasion. It suffices in travelling over almost the same ground to bear a few yards more to the right or to the left and the whole aspect changes and the range of subjects is altered. It is doubtful if anyone, however patient and insensible to fatigue, will be in a position to say that he has really seen the whole of the exhibits. Even if only a limited number of subjects are selected for study and examination the exhibits relating thereto are so scattered and so far apart that it requires much time and patience we find them all out. For instance, in regard to hygiene there is a part of the American sanitary exhibits at the farthest end of [illegible] Then, though the buildings [illegible] sections of hygiene and of [illegible] he river side beyond the Po[illegible] Avenue of Nations in the pavilions of Monaco, Finland, Roumania, and Luxembourg plans for draining various towns, &c. Again, all that relates to the sanitation of Paris, as I have already described, is exhibited in a large, separate, and interesting pavilion, but this is on the other side of the river. Then the medical ar[illegible] exhibits are ever so far away by the Eiffel Tower, [illegible] several foreign countries are [illegible] ss village above the food products and at the extreme end of the old Gallery of Machines. To go to these different hygiene exhibits—and I have not mentioned them all—means a walk of some four miles, and on the road many other subjects would attract the attention of a medical man or a sanitary reformer as bearing indirectly on the questions taken in hand. For instance, in the hygiene section there is a specimen of an hotel bedroom. This is an invasion of the sanitary department by the furniture department, and yet what could be more appropriate? The exhibit is made by the French Touring Club and a very excellent idea it is. The Touring Club intend their exhibit to be an object-lesson to hotel proprietors, especially in Alpine districts where there is a constant flow of tourists who rarely remain more than a night or two. The exhibit shows how bedrooms should be furnished so as to secure the highest degree of cleanliness and the greatest immunity from vermin and from disease. The walls, of course, are rounded off at the angles and covered with a glazed material that can easily be washed, the bed is of iron, the furniture is simple, and the windows are contrived so that they may be opened at the top. Here, by the way, wire gauze should be provided, so that while the air is let in the mosquitoes may be kept out. The most original suggestion is with regard to the floor. Underneath the boards the plaster of the ceiling of the room below is covered over with a bituminous coating which prevents the plaster from disintegrating and the dust from rising up through the chinks of the flooring. Here, then, the connexion between furniture and hygiene is demonstrated, and thus, indeed, all that relates to our homes, whether it be the furniture in the rooms or the way these rooms are built, forms part of the science of hygiene. The same may be sai[illegible] just as anxious that the [illegible] underwear should be [illegible] of our rooms should not be heavily [illegible]

DUST AND LUNG DISEASES.

Take another example. A surgeon proceeds direct to the medical section in the great westerly wing of the main building on the Champs de Mars. He emerges therefrom and at once comes upon the exhibits of the means of transport. This is not medicine or surgery, but how important is the question of transport to most practitioners. Here there are the very latest devices in regard to motor-cars, and here also are ideal broughams and an endless variety of bicycles. Then, having seen the latest improvements, who could resist going a step further to review the retrospective exhibits—the

not to advocate this above any other locality, but to make known the existence, about 10 miles from the town of Harrismith, of what is a considerable rarity upon the high veldt—a large and comfortable farmhouse where paying guests are welcome. Of this house and its hospitality I had in the early part of last year two months' personal and happy experience; and I have lately heard that the host and his wife, both loyal English Afrikanders, have survived the dangers and hardships of the war and are once more in a position to do their best for a limited number of visitors It would give me pleasure to impart to anyone, medical or lay, all that I know about this house and its surroundings.

I am, Sirs, yours faithfully,

W. Lee Dickinson.

9, Chesterfield street, Mayfair, W., Oct. 12th, 1900.

THE CAUSATION OF SCURVY.

To the Editors of The Lancet.

Sirs,—Being much interested in scurvy I read with great expectation the article by Dr. Vaughan Harley and Mr. F. G. Jackson in The Lancet of April 28th, 1900, p. 1184, and that by Staff Surgeon W. E. Home, R.N., in The Lancet of August 4th, p 321, and I regret to say that I am disappointed, for the following reasons.

Dr. Harley, as the result of feeding monkeys with bad meat, came to the conclusion that scurvy is caused by some poison in tainted (flesh) food. Now this may or may not be correct, but it quite fails to account for the disease in men who only eat good grain stuffs. I have seen a good deal of scurvy amongst non-meat-eating Indian troops both on service and in peace time, and have always found it to be caused solely by a diet containing too little fresh vegetables or fruits. I am of opinion that the disease was so caused as it was always cured by the addition to the diet of fresh potatoes, or dates, or limes, without any change being made in the food and water the patients were originally taking, without change of locality or circumstances, and without drugs. I am unable to give an opinion as to the prophylactic or curative powers of tinned milk, of pressed vegetables, of onions, of preserved limejuice, of fresh meat, or of fresh milk, though a recent experience of mine seemed to show that those men who could afford to buy milk were not attacked, while others under exactly the same conditions, but without milk, were attacked, and as regards fresh meat Nansen has proved that a diet of that alone is quite sufficient.

Staff-Surgeon Home suggests that scurvy is "an infection of the mouth with micro-organisms out of decayed food." I do not think that this is so, as in large outbreaks I have seen amongst non-meat-eating men, the various grains which formed the food staples were excellent, and the affection of the gums was not the first symptom observed. Also the gums are not in a state of inflammation—gingivitis. At a certain stage of the disease—generally early, very occasionally late, and I have read sometimes not at all—they become swelled by the scorbutic fibrinous infiltration (except places where teeth are absent), and any ulceration which may supervene later is quite unspecific. With reference to the "orthodox view" given by Staff Surgeon Home let me give a typical case. A healthy sepoy, living in cantonments, wishes to save money. He has to pay for and eat the flour, rice, or dhal cooked by his company cook, so he saves by depriving himself of extras such as milk and vegetables, and meat if a meat-eater. In two or three months that man will be in hospital with scurvy, and in a fairly short time he will, by the simple addition of fresh limes or potatoes to his original diet, be quite fit for duty. "Preceding hardships" are not required for the production of scurvy, and I think it a good working rule to fear that men will become scorbutic if they cannot get either green vegetables, or fruit, or fresh milk, or fresh meat.

I am, Sirs, yours faithfully,

C. B. Maitland, F.R.C.P. Edin.,
Lieutenant Colonel I M S.

Grantown-on Spey.

"TWO CASES OF ARTERIO-VENOUS ANEURYSM."

To the Editors of The Lancet.

Sirs,—I am much interested in the two cases of arterio-venous aneurysm reported in The Lancet of Oct. 13th, (p. 1073) by Lieutenant-Colonel J. T. Lewtas, I.M.S. The result of the first case, treated by ligature of the vein by means of two ligatures applied one above and one below the opening into it and by ligature of the artery above the opening into it, is eminently satisfactory, for the disease was cured and the limb was saved. The result of the second case is, I should consider, eminently unsatisfactory, for the limb was amputated. I have on one occasion tied the artery above the opening into it for the cure of arterio-venous aneurysm of the popliteal artery and vein with the same unfortunate result as that following Colonel Lewtas's operation and it is curious how frequently gangrene has followed this procedure. Gangrene is much more common in cases of femoral arterio venous aneurysm after ligature of the artery by a single ligature applied to the vessel above the opening into it than when a ligature is applied above the aneurysm for the cure of popliteal aneurysm (Hunter's operation). I do not know that this is to be wondered at, but it is certainly true. On the other hand, tying both artery and vein above and below the opening into them and dissecting out the sac has been attended by most satisfactory results. This is undoubtedly a severe and sometimes a difficult operation, but it can usually be performed. In one case reported by Dr. Keen where the common carotid and the jugular veins were involved it was found impossible to dissect out the sac, but even this case was cured.—I am, Sirs, yours faithfully,

Frederick Page,
Professor of Surgery, Durham University.

Newcastle-upon Tyne, Oct. 15th, 1900.

"THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY AND THE GENERAL MEDICAL COUNCIL."

To the Editors of The Lancet.

Sirs,—In reply to Mr. T. Bryant's letter, dated May 5th, published in The Lancet of Oct. 13th (p. 1097), I beg leave to say that I still regard as accurate the statement contained in the second paragraph of that letter. The paragraph is printed between inverted commas and is quoted from the last annual report of my society. I know no reason why anyone should accept as convincing Mr. Bryant's expression of his personal opinion concerning the cases to which he refers; and I see nothing more in his letter than a mere expression of his personal opinion.

I am, Sirs, yours faithfully,

Hugh Woods,
Honorary General Secretary.

Oct. 15th, 1900.

"THE SMOKE NUISANCE."

To the Editors of The Lancet.

Sirs,—In answer to the letter from Mr. F. W. Alexander on the above subject which appeared in The Lancet of Oct 13th, (p. 1098) I should like to point out that the Coal Smoke Abatement Society is well aware that it or any individual may prosecute in a case of smoke nuisance, but that having considered the matter in all its bearings the committee of the society has determined, at any rate for the present, not to institute proceedings itself. The principal difficulty in the society instituting proceedings is that the society would have to prove in court a nuisance by the smoke, a not always easy thing to prove to the satisfaction of a magistrate, whereas if the vestry prosecutes it only has to prove that black smoke was emitted, which under Section 23 and 24 constitutes a nuisance. Where there are public authorities constituted for the purpose of suppressing these nuisances my committee considered that it would be unwise of them to commence legal proceedings in cases which now number some thousands.—I am, Sirs, yours faithfully,

H. A. Des Vœux.
Hon. Treasurer, Coal Smoke Abatement Society.

Oct. 17th, 1900.

NOTES FROM INDIA.

(From our Special Correspondent.)

The Medical Staff for the China Expeditionary Force.—The Hospital Ship Gwalior.—Beri-beri on H.M.S. Sphinx.—The Pasteur Institute at Kasauli.—Further Increase of Plague in India.

One hundred and thirty medical officers (all but eight of whom belong to the Indian Medical Service) having been detailed for duty with the China Expeditionary Force there

has been a great strain on the medical service. Many officers (87) have been taken from civil employment and others holding civil stations have been given charge of native troops in addition to their own duties. Besides this the Government have found it necessary to engage the services of [illegible] practitioners.

[illegible] which has been provided by [illegible] sail on Sept. 22nd. She is one [illegible] India line. Extensive and [illegible] made. She was first carefully [illegible] was then dressed in a coat of light-grey paint with red crosses on her bows, sides, stern, and funnel. She is now lighted throughout by electricity and she has electric fans. There will be separate accommodation for convalescents and a completely isolated infectious ward on the poop A simple and efficacious method of taking the sick on board has been fitted by means of a large port in the ship's side with a conveyance by a light trolly to the beds. For fracture and certain surgical cases swinging beds have been provided. Electric stoves have been [illegible] be boiled in a few minute[illegible] only with all the necessary [illegible] a tropical climate but with all the necessary warming arrangements to cope with the severe winter months of Northern China. The vessel is a three-masted steamer of 4200 tons register and she closely resembles the hospital ship *Carthage*. There will thus be, including the *Maine*, three vessels in Chinese waters, so that with the three base hospitals the sick and wounded should be well provided for. The expenses of the *Gwalior* will probably exceed £100,000 and she will have to be restored to her owners in her original condition

Five cases of beri-beri have occurred amongst the bluejackets on board H.M.S. *Sphinx*, which left Muscat on Sept. 13th and arrived in Bombay on the 17th. The vessel has been placed in quarantine and has been thoroughly disinfected and the patients have been removed to hospital

In consequence of the artificially-induced opposition to the Pasteur Institute at Kasauli it is advisable to record the success which has attended the institution since its opening on August 9th. There have now been 42 admissions, and 31 *patients* have completed the course of treatment. During the past week a British soldier and two native civilians were admitted, while four officers from Bombay, a British soldier, and two native civilians are on the way. The native patients include both Mohamedans and Hindoos, and all appear only too anxious to avail themselves of the treatment.

While plague is again on the increase the numbers under famine relief are rapidly diminishing. The total figures have decreased by nearly half a million during the week and at present there remain one and a quarter millions on relief works and two and a half millions on gratuitous relief. This week's plague [illegible] increase, the total deaths [illegible] 136. Bombay city returns [illegible] Calcutta 81 (including suspected), and Bengal districts 22 In the Mysore State the deaths numbered 363. There are now indications that the disease is again developing in Bombay city, the general mortality (1084, equal to 66 44 per mille) not *only remaining* very high, but the recorded deaths from plague having increased. In Calcutta, although the plague deaths continue much the same as for many weeks past, the general mortality is increasing. The districts of Poona, Nasik, Surat, Thana, and Belgaum give cause for *great anxiety*. Cholera is raging severely in Kashmir, especially in Srinagar and the surrounding districts. It has rapidly gone down in Bombay city and very few cases are now occurring in the army [illegible] served in connexion with [illegible] been finally settled by the [illegible] on them published b[illegible] principles harmonise with [illegible] reigned in Bengal, so that it is not surprising to hear that the Lieutenant-Governor considers that the work of the Bengal Plague Commission is no longer necessary. The Local Commission has therefore been dissolved.

Sept. 20th.

BRISTOL EYE HOSPITAL.—The committee of the Bristol Eye Hospital have received £1263 as a result of the recent *fête* held at the Zoological Gardens, Clifton.

THE UNIVERSAL EXHIBITION OF PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

THE BELGIAN HYGIENE SECTION.

DRAWN away from the Exhibition by the long succession of International Congresses I feel, now that the eleventh hour is approaching, how little I have seen and described of this most marvellous accumulation of the world's wonders. Every visit means the discovery of something new, something which had been missed on a previous occasion. NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Medical Staff for the China Expeditionary Force.—The Hospital Ship Gwalior.—Beri-beri on H.M.S. Sphinx.—The Pasteur Institute at Kasauli.—Further Increase of Plague in India.

ONE hundred and thirty medical officers (all but eight of whom belong to the Indian Medical Service) having been detailed for duty with the China Expeditionary Force there

has been a great strain on the medical service. Many officers (87) have been taken from civil employment and others holding civil stations have been given charge of native troops in addition to their own duties. Besides this the Government have found it necessary to engage the services of purely civilian and unofficial practitioners.

The hospital ship *Gwalior* which has been provided by the Maharajah Scindhia is to sail on Sept. 22nd. She is one of the boats of the British India line. Extensive and costly alterations have been made. She was first carefully surveyed in the dry dock and was then dressed in a coat of light-grey paint with red crosses on her bows, sides, stern, and funnel. She is now lighted throughout by electricity and she has electric fans. There will be separate accommodation for convalescents and a completely isolated infectious ward on the poop. A simple and efficacious method of taking the sick on board has been fitted by means of a large port in the ship's side with a conveyance by a light trolly to the beds. For fracture and certain surgical cases swinging beds have been provided. Electric stoves have been furnished and with these water can be boiled in a few minutes. The *Gwalior* has been fitted not only with all the necessary apparatus of ventilation for use in a tropical climate but with all the necessary warming arrangements to cope with the severe winter months of Northern China. The vessel is a three-masted steamer of 4200 tons register and she closely resembles the hospital ship *Carthage*. There will thus be, including the *Maine*, three vessels in Chinese waters, so that with the three base hospitals the sick and wounded should be well provided for. The expenses of the *Gwalior* will probably exceed £100,000 and she will have to be restored to her owners in her original condition.

Five cases of beri-beri have occurred amongst the bluejackets on board H.M.S. *Sphinx*, which left Muscat on Sept. 13th and arrived in Bombay on the 17th. The vessel has been placed in quarantine and has been thoroughly disinfec
o hospital.

In
opposition to
the P
e to record the
success which has attended the institution since its opening on August 9th. There have now been 42 admissions, and 31 patients have completed the course of treatment. During the past week a British soldier and two native civilians were admitted, while four officers from Bombay, a British soldier, and two native civilians are on the way. The native patients include both Mohamedans and Hindoos, and all appear only too anxious to avail themselves of the treatment.

While plague is again on the increase the numbers under
famine
have dec
at prese
works and two and a half millions on gratuitous relief. This week's plague returns show a further increase, the total deaths throughout India having risen to 1136. Bombay city returns 72, Bombay districts 593, Calcutta 81 (including suspected), and Bengal districts 22. In the Mysore State the deaths numbered 363. There are now indications that the disease is again developing in Bombay city, the general mortality (1084, equal to 66.44 per mille) not only remaining very high, but the recorded deaths from plague having increased. In Calcutta, although the plague deaths continue much the same as for many weeks past, the general mortality is increasing. The districts of Poona, Nasik, Surat, Thana, and Belgaum give cause for great anxiety. Cholera is raging severely in Kashmir, especially in Srinagar and the surrounding districts. It has rapidly gone down in Bombay city and very few cases are now occurring in the army. The principles to be observed in connexion with plague operations have apparently been finally settled by the recommendations of tl
e resolu-
tions on them publishe
These
principles harmonise
ll along
reigned in Bengal, so that it is not surprising to hear that the Lieutenant-Governor considers that the work of the Bengal Plague Commission is no longer necessary. The Local Commission has therefore been dissolved.

Sept. 20th.

BRISTOL EYE HOSPITAL.—The committee of the Bristol Eye Hospital have received £1263 as a result of the recent *fête* held at the Zoological Gardens, Clifton.

THE UNIVERSAL EXHIBITION OF PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

THE BELGIAN HYGIENE SECTION.

DRAWN away from the Exhibition by the long succession of International Congresses I feel, now that the eleventh hour is approaching, how little I have seen and described of this most marvellous accumulation of the world's wonders. Every visit means the discovery of something new, something which had been missed on a previous occasion. It suffices in travelling over almost the same ground to bear a few yards more to the right or to the left and the whole aspect changes and the range of subjects is altered. It is doubtful if anyone, however patient and insensible to fatigue, will be in a position to say that he has really seen the whole of the exhibits. Even if only a limited number of subjects are selected for study and examination the exhibits relating thereto are so scattered and so far apart that it requires much time and patience we find them all out. For instance, in regard to hygiene there is a part of the American sanitary exhibits at the farthest end of the Esplanade des Invalides. Then, though the buildings specially denominated as the sections of hygiene and of warming and ventilating are on the river side beyond the Pont de l'Alma, there are in the Avenue of Nations in the pavilions of Monaco, Finland, Roumania, and Luxembourg plans for draining various towns, &c. Again, all that relates to the sanitation of Paris, as I have already described, is exhibited in a large, separate, and interesting pavilion, but this is on the other side of the river. Then the medical and surgical exhibits are ever so far away by the Eiffel Tower, while the sanitary exhibits of several foreign countries are still further off by the Swiss village above the food products and at the extreme end of the old Gallery of Machines. To go to these different hygiene exhibits—and I have not mentioned them all—means a walk of some four miles, and on the road many other subjects would attract the attention of a medical man or a sanitary reformer as bearing indirectly on the questions taken in hand. For instance, in the hygiene section there is a specimen of an hotel bedroom. This is an invasion of the sanitary department by the furniture department, and yet what could be more appropriate? The exhibit is made by the French Touring Club and a very excellent idea it is. The Touring Club intend their exhibit to be an object-lesson to hotel proprietors, especially in Alpine districts where there is a constant flow of tourists who rarely remain more than a night or two. The exhibit shows how bedrooms should be furnished so as to secure the highest degree of cleanliness and the greatest immunity from vermin and from disease. The walls, of course, are rounded off at the angles and covered with a glazed material that can easily be washed, the bed is of iron, the furniture is simple, and the windows are contrived so that they may be opened at the top. Here, by the way, wire gauze should be provided, so that while the air is let in the mosquitoes may be kept out. The most original suggestion is with regard to the floor. Underneath the boards the plaster of the ceiling of the room below is covered over with a bituminous coating which prevents the plaster from disintegrating and the dust from rising up through the chinks of the flooring. Here, then, the connexion between furniture and hygiene is demonstrated, and thus, indeed, all that relates to our homes, whether it be the furniture in the rooms or the way these rooms are built, forms part of the science of hygiene. The same may be said with regard to clothing, and we are just as anxious that the dyes used in making our clothes and underwear should be non-poisonous as that the wall-paper of our rooms should not be heavily loaded with arsenic.

DUST AND LUNG DISEASES.

Take another example. A surgeon proceeds direct to the medical section in the great westerly wing of the main building on the Champs de Mars. He emerges therefrom and at once comes upon the exhibits of the means of transport. This is not medicine or surgery, but how important is the question of transport to most practitioners. Here there are the very latest devices in regard to motor-cars, and here also are ideal broughams and an endless variety of bicycles. Then, having seen the latest improvements, who could resist going a step further to review the retrospective exhibits—the

first bicycles and many quaint old carriages and coaches. While engaged in this department the visitor will come upon the sanitary exhibits of Belgium. These are situated against the wall nearest to the Avenue de Suffren and face the carriages and coaches, the sledges, the sedan chairs, &c. Why Belgian sanitation should be amid the means of transport while the sanitary exhibits of Germany, Austria, England, and other countries are placed over and above the food supplies of the world, is one of those mysteries which is not easily explained. As, however, Belgium is among the most progressive of European countries in regard to sanitation, it is to be hoped that visitors have found their way to this section in spite of its inappropriate localisation. In any case, it has not escaped the attention of the jury, for they have awarded to the Belgian sanitary exhibits no less than two grand prizes, nine gold medals, seven silver medals, seven bronze medals, and three honorary mentions. The Belgian Government deputed Dr. Bonmarriage, founder of the Brussels Institute of Hygiene, to organise this section, and he has succeeded in gathering together a great amount of useful informative matter. From his own institute he sends, among other things, sections of the lungs of rabbits and micro-photographic slides of the same. These rabbits were exposed to the action of various forms of dust which in divers industries workmen have to breathe. We are thus able to see the lesions produced in the lungs by coal-dust, the dust of mills, of hemp, of cement, &c. He hopes by these means to demonstrate the necessity of greater care and better ventilation, and thus to reduce the prevalence of diseases of the chest in various industries. Professor Henri and Professor Albert Bergé of the Brussels University exhibit their method of sterilising water by the oxidising effects of a mixture of chlorate of potash and a weak solution of sulphuric acid. A current of air carries the gas evolved into a small quantity of water, and this latter is mixed with the water that has to be purified. This process can be employed both for small quantities of water and for large quantities. At Ostend 5000 cubic metres of water per day are thus sterilised. On the other hand, travellers can carry a small bottle of the solution with them, and with the aid of a pipette can sterilise a glass of water as it stands on the table while they are dining.

THE PRESERVATION OF CORPSES.

Close by, Dr. G de Richter and M. F. de Recher, a civil engineer, exhibit their method of preserving dead bodies with formalin. The system is based on the penetrating powers of this antiseptic. To ensure this penetration the case in which the body is placed is divided into two. The body is placed in the upper portion, over a chamber or partition for the evaporation of the formalin. The formalin of commerce is employed. There are four recipients automatically fed and a slight current of air is provided to facilitate the evaporation The formalin runs along channels over which wicks are suspended which take up the liquid and still further help its evaporation. Thus a minimum amount is spread over a maximum surface, and this maintains the air in a constant state of saturation. The body absorbs the formaldehyde (CH_2O), but it is constantly renewed by the evaporation of the formalin. One litre of formalin suffices for the treatment of a human body, therefore the process is much cheaper than that of refrigeration. On the other hand, it does not in any way interfere with any toxicological researches that may subsequently have to be made. The most remarkable fact is that when a body has been treated in this manner for four weeks it is not only sterilised but it will not decompose and it may be kept in the open air for an indefinite period. Thus a photograph is shown of a man who died from tuberculosis on Oct. 10th, 1898. The body was placed in the apparatus from Oct. 12th to Dec. 6th, and then laid out on a table in the open air. The photograph was taken in May, 1899, five months after the body had been thus exposed, and it was unaltered. This is, then, a great improvement on the old process of embalming as it does not necessitate the mutilation of the corpse. The process can also be applied to an ordinary coffin, and if the lid is partially of glass the body or the face may be seen intact years after death. Thus there is a photograph of a person who was placed in a coffin of this description on Dec. 8th, 1898. The photograph was taken in the month of May last. The body was then intact and it is stated that it remains in that condition at the present day. The process will render great service in medico-legal matters and for the preservation of anatomical material or of the bodies of animals and for the sterilisation of the bodies of persons who have died from infectious diseases, or for keeping the bodies of persons who have died at sea.

COMPRESSED AIR IN MINES.

M. Hanarte, civil engineer, exhibits an apparatus for the economic production of compressed air which is extensively used in the Belgian and French coal-mines. By special methods he dispenses with the aid of heat and thus reduces the first cost. The most ingenious device is the application of this compressed air as the motive power for working the drilling and other machinery used in the mines, so that the cost of compression is compensated by the economy of the cost of motive power, but from the health point of view the invention is still more important. The discharge of the compressed air provides a supply of pure air and this takes place precisely where the usual or general ventilation of the mines is least efficacious. Where there is a gallery that is open at both ends ventilation is comparatively easy, but miners generally work in holes, caves, or passages that have no opening at the other end and where it is not possible to establish a through draught. The discharge of compressed pure air at the head of such drillings is of the greatest benefit to the workers. It forces the foul air out of the hole and replaces it with pure air. The force supplied can also in many instances be used instead of that of explosives and thus the risk of accidents is reduced. The same system may be applied to workshops and factories and the motive power may be made to serve for ventilation as well as for manufacturing the goods produced.

OTHER BELGIAN EXHIBITS.

The Compagnie Générale des Conduits d'Eau of Liège give some indication of the vast public works which they have undertaken in various countries. The company are amongst the largest manufacturers of metallic pipes for the supply of gas or of water. They can make pipes that will resist a pressure of 150 atmospheres and which vary in diameter from two centimetres to one and a quarter metres. From 70 to 80 per cent. of the pipes they produce are exported to Holland, France, Spain, Roumania, Germany, Bulgaria, Turkey, Egypt, Japan, Siberia, South America, and other countries. The waters supplied to the suburbs of Paris, to the city of Rome and to many Italian towns, to Barcelona and to other Spanish towns, to Bremerhaven, to Utrecht, to Arnheim, to Bucharest, and to Vienna, pass through such pipes. It would be difficult to find a firm with a greater experience of the problem of the distribution of water in large towns. There are many other exhibits here that deal with water-supply, and notably full details are given in respect to the derivation of the springs or watershed of the Bocq for the supply of Brussels, which is the largest of such undertakings. Then, as the municipalities of several towns have made exhibits, these naturally include their system of water-supply. Perhaps the most interesting exhibit of this description is that of the town of Spa. This fashionable pleasure and health resort was formerly so badly drained and so deficient in its water-supply that severe epidemics resulted. As several English visitors were the victims of these unhealthy conditions the British Government made some diplomatic representations on the subject which, with the pressure of public opinion, ultimately produced the desired result and now the town authorities of Spa are quite proud of their new and good water-supply and are anxious to show that they have secured a complete system of sewers and that the branch sewers are all provided with automatic flush-tanks. The vital statistics of the town bear witness to the excellent effect of these reforms. There are any number of plans and drawings of hospitals, asylums, sanatoria, and the like, notably that of the Society of Israelite Mothers presided over by Madame de Rothschild, now Baroness Lambert. There is, first, a lying-in hospital where women, without distinction of creed and whether married or not, are received, but the special feature is that this institution continues to help both mother and child for many years. After the birth outdoor assistance is given, then there is a *crèche* for the child when he is three years old and a school when the age of six years is reached, and every effort is subsequently made to teach him a trade and enable him to earn an independent living. There is likewise an orphan asylum. Every contingency is provided for, and the poor mother and child who are fortunate enough to gain admittance to this institution may consider that they have reached a permanent haven. The jury awarded the gold medal to this charity. The various bacteriological [illegible] s from which a very [illegible] of research may be [illegible] photographs to be [illegible] been attained. Alto- [illegible] conveys a favourable [illegible] gress which has been achieved in that country in regard to sanitation.

Paris, Oct. 15th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Volunteer Medical Staff Corps.

[illegible] W. COATES, command- [illegible] lical Staff Corps, appeals [illegible] dation. "To secure the [illegible] rs with a drill hall are absolutely essential." There is now an opportunity of acquiring land, but to carry out the scheme a sum of £12,000 is required. The appeal is based on the following very good grounds: (1) That companies of the Volunteer Medical Staff Corps are a necessary complement of the volunteer force of the kingdom; (2) that it is an immense advantage to the community that there should be in our midst thoroughly trained men capable of affording efficient assistance in the emergencies of accident and illness in civil life; and (3) that by this means a valuable opportunity is given to the youth of Manchester and district to follow a recreation which should improve both their physical, intellectual, and moral development. The use of the term "recreation" is quite correct, and this one has [illegible] er forms of recreation that the [illegible] is not confined to, or centred [illegible] s shown not only other nations but our own somewhat sceptical people that the volunteers are not merely play soldiers whose exploits are confined to peaceful promenading, but that they form a valuable part of our insurance against foreign aggression, which would not be complete without a due proportion of the medical staff corps. Bearing in mind what has already happened, and also that it is the unexpected that does happen, the Manchester people will surely pay this modest insurance premium.

Early and Improvident Marriages.

At an inquest held recently Mr Smelt, the Manchester coroner, made some remarks on "early and improvident marriages." The mother of a child who had come to his death through burns said that she had been married 17 years and was married at 17. She went out to work for 6*s.* a week, and left the child to take "pot luck," as her husband was earning nothing. Mr. Smelt said that on account of these marriages the English race was a degenerating and miserable race. A Zulu could not marry till he was 25 and possessed a certain amount of property. "In a fight under equal conditions he would back 50 Zulus against 100 men such as some who applied to be admitted into the British army." Whatever may be the value of this special statement there is no doubt of the degeneracy and deterioration of the masses of our town-bred population. It is saddening to see the pallid, stunted, ill set up lads and girls, many of them married, streaming out from the factory gates at closing time, and [illegible] infants, of perhaps [illegible] and the weary carev [illegible] their ill-developed n [illegible] hospitals. Apart from the pity of it, the prospect of a large proportion of the next generation born of such a stock and living under the conditions at present prevailing in our large towns is a serious one for the nation. It suggests the question as to whether the heavy infant death-rate we deplore is a curse or a blessing. How to prevent this decay of our race is a problem which will not be solved under present conditions. Whether our system of education will do anything to give more correct views and to bring about a better mode of living seems more than doubtful.

Manchester Port Sanitary Authority.

A careful watch is maintained against the importation of plague by the Ship Canal. During September last the inspector at Eastham made inquiries as to the health of all on board the 197 vessels that passed through the lock into the port. Of these, 166 were British, 13 were Norwegian, and the rest were German, French, Swedish, and Belgian. On Sept. 3rd Dr. J. H. Crocker, the medical officer of health of the Port of Manchester, paid a special visit to Glasgow, examined all the cases of [illegible] with the houses and areas fr [illegible] the sanitary chambers and [illegible] of the sanitary authority. On his return, after consultation with Dr. J. Niven and Dr. C. H. Tattersall, the medical officers of health of Manchester and Salford respectively, he decided that a medical examination of everyone on board a vessel coming from Glasgow should be carried out. It was arranged with Dr H. A. Bold of Trafford-road, Salford, close to the docks, that he should board the vessels at Mode Wheel and inspect the crews and passengers on the way to the docks During the month 19 vessels from Glasgow and two from foreign infected ports entered the canal, but no case of infectious sickness was found.

Manchester Royal Infirmary.

The Manchester Royal Infirmary loses, in accordance with the rule as to the age-limit, the services of Mr. Walter Whitehead as a member of the active staff, and at a meeting of the board of management he was appointed an honorary consulting surgeon to the institution. Mr. William Thorburn, the senior honorary assistant surgeon, was unanimously appointed honorary surgeon.

Oct. 16th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Inaugural Address by the New Professor of Medicine of the University of Edinburgh.

ON Oct 16th, at two o'clock in the afternoon, in the McEwan Hall, Dr. John Wyllie, the recently appointed Professor of Medicine in the University, delivered his inaugural address before a large concourse of students and others. Professor Wyllie was supported by a number of his colleagues in the Senatus, while the chair was occupied by Sir William Muir, Principal of the University, who briefly introduced the new Professor. Professor Wyllie devoted his opening lecture to the memory of the distinguished men who had occupied the chair in time past He began his address by appreciative notice of the work and influence of Sir Thomas Grainger Stewart, his immediate predecessor. He then considered separately the seven occupants of the chair who preceded Sir Thomas Grainger Stewart—namely, John Rutherford, John Gregory, William Cullen, James Gregory, James Home, William Pulteney Alison, and Thomas Laycock. Having given a brief and judicial summary of the position held by these men he concluded his address as follows: "I feel that it is a very great honour to me that I have been elected to the Chair of Medicine. I feel also that I have taken upon me in accepting the office a very great responsibility. The history of the chair is all too splendid to be studied with perfect comfort by one who now comes for the first time to occupy it. But I trust that the example of the eminent men who have in the past been its occupants will be an inspiration to me and not by its very brilliancy a discouragement. I confess to you that it is to me a matter of great satisfaction that by my appointment to this chair it is determined that in the future my life shall be devoted to the teaching of medicine as it has been in the past and that my charge of wards at the Royal Infirmary will enable me to work towards the advance of medical science. The welcome which to-day you have so kindly given me encourages me to hope that I may be able to discharge my duties in such a manner as may be to the advantage of my students and to the satisfaction of my Principal and my colleagues in the University." The address was listened to in perfect stillness by the large audience, and the outburst of applause at its conclusion was convincing proof of the interest which it had aroused and of the popularity of the new Professor.

Professor Chiene on his Experiences in South Africa.

Professor Chiene opened the winter session of the class of surgery in the University of Edinburgh by an address in which he gave an outline of his experiences as a consulting surgeon in South Africa. The address was delivered in the McEwan Hall on Oct. 16th, when the Professor was given a most enthusiastic welcome by his students. One could better appreciate, he said, after even a short absence immediate relief. There was defective accommodation in the day-rooms, and it was pointed out that the responsibility for the providing of suitable accommodation rested with the committee and that it was necessary for them to satisfy the Lord Lieutenant that the requisite accommodation and buildings had been provided before the rate-in-aid could be paid. The temporary buildings, which were to have been completed in the spring of 1899, had not yet been occupied, nor had the furniture been obtained for them. The overcrowding of the asylum was not only disastrous to the treatment of patients but menaced their safety should any epidemic occur.

Winter Session of the Belfast Medical School.

The winter session (1900-1901) of the Medical School in Belfast began on Oct. 16th. In the morning Dr. H. L. McKisack gave the introductory address in the theatre of the Royal Victoria Hospital when there was a large audience of students and members of the medical and surgical staff. After welcoming the students on behalf of the staff Dr. McKisack referred to the recent losses which they had suffered by the death of Dr. Strafford Smith and by the retirement of Dr. Henry O'Neill. The new Royal Victoria Hospital, of which the foundation-stone is to be laid early in 1901 by H.R.H. the Prince of Wales, was described, and while the advantages to be expected from a thoroughly well-equipped modern hospital were fully acknowledged it was impressed upon the audience that earnestness on the part of teachers and students was the essential, and it was pointed out that much of the real progress had been effected with very simple and often imperfect apparatus. The importance of educating the senses thoroughly was therefore emphasised, whilst the mental education and the use of scientific diagnostic instruments were not to be neglected. The students were advised to strive to grasp the case in all its bearings and not to be content with discovering the pathology of an affected organ. After commenting on the difficulty of erecting a typical case as a standard for comparison and on the constant occurrence of variations, the lecturer summarised the advisory part of his remarks to the students as follows:—"(*a*) Follow the course mapped out for you during the session, without straying aimlessly from ward to ward. (*b*) Learn thoroughly how to examine a case and to take notes of it in a methodical and orthodox manner. (*c*) Follow up your cases perseveringly, examining them frequently and keeping notes of their progress. (*d*) Be as regular and punctual in your attendance at the hospital as at your meals, or, if anything, be rather more so. Come early and do not be in a hurry to get away. You cannot be better employed anywhere else. (*e*) Do not miss any opportunity of coming into the hospital as resident." College lectures began also on Oct. 16th.

Royal Victoria Hospital, Belfast.

Owing to the sad death of Dr. R. S. Smith and the regretted resignation of Dr. H. O'Neill, two important vacancies have occurred, one on the medical side, the other on the surgical side, of the Royal Victoria Hospital staff at Belfast. Dr. H. L. McKisack will succeed to Dr. Smith's place and become full physician, and up to the present Dr. W. B. McQuitty is the only candidate for the position of assistant physician vacant by Dr. McKisack's promotion. On the surgical side, Dr. A. B. Mitchell will become full surgeon, Dr. T. S. Kirk will become senior assistant surgeon, and Mr. Robert Campbell is the only candidate for the junior assistant surgeoncy. For the position of surgical registrar, vacated by Mr. R Campbell, there will be a sharp contest, as already several candidates are in the field.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Giving of Medical Certificates by Hospital Internes.

THE Association of Medical Practitioners in the Department of the Seine has for some time past over and over again had to consider some of the many difficulties which arise concerning the application of the new law dealing with accidents to workmen, especially where the wounded man is taken to a hospital. The insurance companies naturally enough demand a medical certificate as to the extent of the injuries given as soon after the accident as it is possible to form an opinion, so that they shall know whether to impute liability for the accident to the originator of it or to the employer. The administrative body of the hospitals, however, place great difficulties in the way of the medical officers of the insurance companies with regard to their entry into the hospitals for the purpose of satisfying themselves as to the condition of the wounded man. In a recent case a medical student who was employed as *interne* of the ward refused to give entry to the insurance company's medical officer, saying that a recent circular of the director of the Assistance Publique gave *internes* the sole right of giving certificates with regard to hospital cases and that, therefore, he had no information to give. The medical officer of the insurance company remarked that he only wanted a certificate for the company so that it might be able to ascertain when the wounded man would be able to resume work and in particular how much compensation it ought to pay to the family of the workman. The *interne*, however, stuck to his guns and refused any information. The administrative council of the Medical Association of the Seine took up the matter and protested strongly against the attitude of young practitioners who begin their medical career with such an unbrotherly mode of action. It also went into the point whether a certificate granted by a student although an *interne* should be considered really valuable from a medical and legal point of view. Such students are only authorised to perform medical acts inside the hospital by a tolerance established by force of circumstances, but they have no legal right, without paying the proper tax (*patente*), to take responsibility for a written document which will go out of the hospital and eventually come on for discussion in a court of law. Such an act would come under the head of illegal practice of medicine, especially, as must be remembered, when the certificate has to be paid for. A letter was therefore sent to the Minister of Commerce dealing with the subject, and the Minister, who obviously found himself in a tight corner, replied that such a certificate as would be given by an *interne* was not a real certificate, that it was not designed to establish the right as between two adversaries at law, but simply to give an exact account from the beginning of the condition of the wounded man and by giving some indication of the probable results of the accident to enable the alderman of the ward (*maire*) to decide as to whether an inquiry should take place before a magistrate or no. The Medical Association protested against the hair-splitting of this distinction, for it argued that the certificate *was* a certificate and one moreover which was very important, dealing as it did with the conditions existing immediately after the accident—a state of things which certainly could not recur later, and so would be the most important piece of evidence at the trial. Besides, supposing that further explanations were necessary and that the *interne* were called upon to give evidence before the magistrate, would he have to be paid the regular fee due to a medical witness—namely, five francs? If so—and this was a course of events which was quite likely to happen—the reception of this sum, together with that already paid for the certificate, would be a second act of illegal practice. Unfortunately it is much to be feared that the Government, to get out of finding a solution of so difficult a problem, will accept the dangerous ruling of the Minister. On the other hand, it must be remembered that the law of Nov. 30th, 1892, granted certain concessions to *internes* and certain other students which were full of peril to medical practitioners. This law laid it down that such students should be allowed to practise medicine in time of epidemics or while acting as the *temporary* locum-tenent of a medical officer. Practice in the first case can be easily explained; the second concession was demanded by medical men themselves who feared that if ill or very tired they would not be able to get a substitute if they had to employ a qualified man. This, however, is only a temporary concession which has to be obtained previously from the prefect and which lasts for only three months, although renewable at the end of that time. It is this first clause of the law which is the cause of abuses. As a matter of fact, a prefectural order authorises every three months a certain number of students to perform acts of medical practice even when there is no epidemic and no question of filling the place of an absent medical officer. The object is to assure immediate attendance for urgent cases, so that they should not have to wait unattended for the visit of the surgeon of the day or until the following morning when the chief medical officer of the ward pays his visit. This, however, is no ground for arguing that such students have the right to give certificates in case of accident for use outside the hospital. An injured workman or his employer has 48 hours' grace before he must hand over certificates at the Mairie. Such a certificate could easily be given on the following morning by the principal medical officer of the ward, at least in all cases where an immoveable dressing did not prevent a clear statement as to the injuries being drawn up. The president of the Medical Association is of opinion that "the hospital medical officer cannot be considered to be replaced by his *interne* while he continues to practise in the same town." The replacing can only be considered as genuine if the medical officer is really absent or has left off work for the time being. Unless such is the case it would be inconceivable that a practitioner with one diploma and who had paid only his own tax should be able to practise by means of an intermediary. In these circumstances the Medical Association has appointed a committee which after due inquiry will decide as to whether the order of the Prefect of the Seine giving to *internes* the right to practise in hospitals should not be annulled by the Conseil d'Etat.

The Prophylaxis of Plague.

A recent order of the Minister of the Interior decrees that ships [illegible] recognised as infected with [illegible] ch has come indirectly from [illegible] or discharge cargo at any port of France or Algeria, except Dunkirk, Havre, St. Nazaire, Pauillac, Marseilles, or Algiers. The Minister of the Interior will from time to time give notice of other ports which may under exceptional circumstances be thrown open to the above-mentioned description of vessels, due regard being had to the ship's bill of health and the bill of lading.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Health of New South Wales.

THE report of the Board of Health of New South Wales for 1693 has just been presented to Parliament. "The population "is increasing at a rate such as to have led to its having become more than trebled during the 30 years covered by the censuses; the increase is partly due to natural increment and partly to immigration. The mean annual birth-rate for 10 years was 32·61 per 1000 of the population," but the Board noted with regret a continued fall in the mean annual birth-rate. The general death-rate had, however, also diminished, but the Board

regrets that while the death-rate of children under one year is [illegible]

native birth who had never left New South Wales, and two were Chinese males.

The medical officer of health of the Hunter River combined sanitary districts, Dr. Robert Dick, has also sent in his report for the year 1899. He stated that the local authorities in the district had shown more activity in sanitary matters, though deficient in regard to thorough disinfection after cases of infectious disease and in systems of refuse removal, &c. Fewer deaths occurred from typhoid fever, influenza, measles, diarrhœa, and respiratory diseases other than phthisis. In many towns in the district cesspits still existed and the greater incidence of typhoid fever in houses with cesspits was very marked. In the town of Wickham the ratio was 1 case of typhoid fever to every 100 houses where pail-closets were used and 1 to every 48 houses where cesspits existed. An inspection of the whole of the dairies in the district showed a steady improvement in their sanitary conditions.

Isolation Treatment of Consumption.

A deputation recently waited on the Government of Queensland with a request that measures should be taken to provide for the isolation and separate treatment of persons suffering from consumption. The deputation pointed out that all that could be done at present was the establishment of hospitals for the reception of a percentage of those afflicted with the disease.

Regulations for Patent Medicines.

The same deputation also urged the Government to take some steps to regulate the sale of patent medicines and to insure the public against fraud. It was suggested that the Government should see that all proprietary medicines were analysed and their exact composition made known, and that the sale of such as were dangerous should be suppressed.

The North Sydney Hospital.

Some years ago a small cottage hospital was established in North Sydney. Since then the population of this division of the metropolis has increased to between 50,000 and 60,000 inhabitants, but nothing has been done to increase the hospital accommodation, which is utterly inadequate, and patients have to cross the harbour to the other hospitals which are also overcrowded. A deputation recently waited on the Government to ask for a grant of £20,000 for the erection of new buildings. The Colonial Secretary gave a favourable reply and promised to put this amount on the estimates. In his reply the Colonial Secretary observed that notwithstanding the liberal expenditure on hospitals recently the demand continued to outstrip the supply, and he "was afraid the hospitals were being made too attractive and were abused, patients preferring the treatment available to that which they could get at their own homes."

Obituary.

Deep regret was felt in Australia at the announcement of the death in England of Dr. Alfred Shewen who left Sydney about six months ago for a holiday trip to England in the hope that it would restore his failing health. Dr. Shewen came to New South Wales soon after taking his M.D. degree in 1873 and began practice as a physician in partnership with the late Dr. Fortescue. He soon reached a very high position and gained a large practice. He was one of the first honorary physicians at the Prince Alfred Hospital, Sydney, and was joint lecturer on clinical medicine at the university and a frequent contributor to the local medical societies and journals. He was extremely popular with both the public and the profession and was only 56 years of age at the time of his death.—Mr. Edward Hyacinth O'Doherty died suddenly at Brisbane on July 5th and his funeral was attended by nearly every medical man in Brisbane. He was educated at the Brisbane Grammar School and studied medicine in Dublin, returning to Brisbane in 1882 and joining his father, Dr. K. I. O'Doherty, in practice. For 17 years he was medical officer to out-patients at the Brisbane Hospital and latterly he was honorary physician. For many years he was a member of council of the Queensland Branch of the British Medical Asso- [illegible] and in 1897 he was President. He was exceptionally [illegible] with all classes; full of genial good humour, uni[illegible]y courteous and sympathetic, and often brilliantly [illegible] his charm was felt by everyone. He was remarkable [illegible] loyalty to the profession, and all these qualities, combined with professional skill of no mean order, secured him success. His sudden death came as a great shock to the community.—The late Miss Dagmar Berne was one of the best known and most successful of the women practitioners in Sydney. She matriculated at Sydney University in 1888 and was a student at the Sydney Medical School for a time. She then went to London and Edinburgh, and was at the [illegible] Dublin for a year and returning to London [illegible] the Women's Hospital. She [illegible] in 1895 and continued in full [illegible] was attacked with phthisis and died suddenly from hæmorrhage on August 21st.

Sept. 8th.

Medical News.

KING'S COLLEGE, LONDON.—The following Entrance Scholarships have been awarded in the Medical Faculty:—Warneford Scholarships, £75 each: R. Taylor and A. M. Pollard. Medical Entrance Scholarship, 60 guineas: T. J. Miller. Sambrooke Medical Scholarships: £60, R. H. C. Gompertz; £40, A. D. Griffith. Open to all Faculties:—Clothworkers' Science Scholarships: £30 for two years, W. J. Marlow; and £20 for two years, O. C. Thompson. Engineering Entrance Scholarships: £15, N. G. Langrish; £10, J. H. P. Billrough; and £10, F. R. Fairmaner.

ST. GEORGE'S HOSPITAL SCHOLARSHIPS.—The following scholarships have been awarded for 1900: an Entrance Scholarship in Arts of the value of £150, Mr. Valentine Henry Blake; an Entrance Scholarship in Arts of the value of £50, Mr. James Aubrey Torrens, of St. Paul's School; an Entrance Scholarship in Science of the value of £85 Mr. Basil Nelson Tebbs, M.A., of Queen's College, Cambridge; an Entrance Scholarship in Science of the value of £42 10s., Mr. John Douglas Hope Freshwater, B.A., of Trinity College, Cambridge; and an Entrance Scholarship in Science of the value of £42 10s., Mr. Harry Bertram McCaskie, B.A., of Caius College, Cambridge.

MEDICAL FEES FOR LUNACY CASES.—The Devonport Board of Guardians consider that the sum of one guinea is too large a fee for medical men to be paid in pauper lunacy cases and recently approached the borough magistrates with a view to having the fee reduced. At the meeting of the guardians held on Oct. 12th it was reported that the magistrates did not share the opinion of the guardians. Eventually the board decided to write to the members of the medical profession in Devonport asking them if they would accept a fee of half a guinea for these cases, and the matter will be again brought before the magistrates

MEDICAL FACULTY OF UNIVERSITY COLLEGE, LIVERPOOL: OPENING OF THE WINTER SESSION.—The winter session of the Medical Faculty of University College, Liverpool, was inaugurated on Oct. 13th under auspicious circumstances The gathering included the Lord Bishop of Liverpool (Dr. Chavasse), who delivered the opening address and distributed the prizes; the Lord Mayor of Liverpool, the Earl of Derby, and other prominent Liverpool citizens. The Dean of the Medical Faculty (Professor A. M. Paterson) reported the progress made by the several departments during the past year, a *résumé* of which has already appeared in the columns of THE LANCET.[1] Each year brought additional valuable prizes for the students of the faculty. Two university fellowships, each of the value of £100 for one year, were now open to medical graduates of the Victoria University and were offered to encourage research at the close of the period of study. A colonial fellowship in pathology and bacteriology of the value of £100 a year for five years has been presented by Mr. William Johnston, and a medal in pathology, to be called the "Kanthack Medal," in memory of the late Professor Kanthack of Cambridge, a former distinguished student of the Liverpool School, was awarded now for the first time. The department under the guidance of Dr. Henry Briggs, the professor of midwifery and gynæcology, had been laudably active during the past year. Professor Briggs has brought his department to a high state of efficiency and has spared neither time nor money to effect that object. Formerly Liverpool students were forced through lack of means to seek midwifery instruction elsewhere, but now all but two students had obtained their midwifery curriculum in Liverpool. The Bishop of Liverpool, having distributed the prizes, expressed his deep interest in the fortunes of the young and vigorous University College of Liverpool, and dealt in a very interesting manner with the life and work of William Harvey, John Hunter, and Thomas Sydenham. His best wish for the students was that they might unite the culture of Harvey with the industry of Hunter and crown both with the love of truth, the love of God, and the love of man, which were the glory of Thomas Sydenham.

A NEW dog-muzzling order, enforced on Oct. 15th, has been issued for Carmarthenshire.

ACCIDENT TO A GERMAN PROFESSOR.—Professor Rieder of Bonn, who has been entrusted with the reorganisation of the Turkish Medical Department, has met with a serious accident. While superintending the building of a hospital in Constantinople he fell a distance of 45 feet which resulted in an injury to the spine and a fracture of the foot.

SCARLET FEVER IN THE RHONDDA VALLEY.—Owing to the prevalence of scarlet fever in the Rhondda Valley the district council has called upon the school board to close seven of the public elementary schools for a period of six weeks. The outbreak began about a fortnight after the schools reassembled; the weekly number of cases since then has averaged nearly 60.

WATER-SUPPLY OF FALMOUTH.—At a meeting of the Falmouth Corporation held on Oct. 9th, a resolution was passed by 11 votes to two in favour of purchasing the waterworks of the town. A meeting of the ratepayers will be called to consider the matter. It is estimated that the sum of £74,500 will be required to purchase the waterworks and to carry out the necessary improvements.

FREEMASONRY.—*The Rahere Lodge, No. 2546.*—An ordinary meeting of the Rahere Lodge was held at Frascati's Restaurant, Oxford-street, W., on Tuesday, Oct. 9th, W. Bro. Walter Gripper, M.B., being in the chair. Bro. W. E. Bennett, F.R.C.S., was admitted to the third degree and Mr. R. H. Wellington, M.R.C.S., L.R.C.P., was initiated into Freemasonry. Subsequently some 30 brethren dined together.

UNIVERSITY OF CAMBRIDGE.—The Medical and Surgical Examinations this term will begin as follows: First M.B. (Chemistry) and Second M.B. (Anatomy and Physiology), Dec. 10th; Third M.B., Dec. 11th; First M.B. (Biology) and Second M.B. (Pharmacy), Dec. 13th; and M.C., Dec. 18th. On Oct. 11th the degree of M.D. was conferred on Robert Derwent Parker, B.A., M.B., B.C., of Gonville and Caius College.

VACCINATION EXPENDITURE.—At the meeting of the Devonport Board of Guardians held on Oct. 12th the vaccination committee, reporting upon vaccination fees, stated that they recognised that if vaccinations were to be performed successfully they must be paid for, and that the notable increase in the cost of each individual case was on account of the large amount of work entailed upon the public vaccination officers by the Order of 1898.

TYPHOID FEVER IN SOUTHWARK.—Dr. F. J. Waldo, medical officer of health of St. George-the-Martyr, Southwark, has reported to the vestry—at the request of the Local Government Board—on an outbreak of typhoid fever within the parish. He said that 102 cases of fever had occurred between Sept. 14th and Oct. 8th, of which number two had already died. 97 of the cases came from an infected area situated in the north-east portion of Ward 1—the poorest part of the parish. Many of those attacked lived in Queen's-buildings, which housed upwards of 3000 persons on three acres, and in Grotto-place, which was officially represented as an unhealthy area in 1899, but which had not yet been dealt with by the county council. A large proportion of those attacked were children of school age. There was no evidence of specific pollution of the drinking water, which was drawn from two companies which supplied the infected houses in about equal proportions. The milk-supply came from various sources and was free from the specific poison of typhoid fever. Many of the house-drains were defective and the sewers were either imperfectly ventilated or were not ventilated at all. The sewers in at least three streets had been condemned by the surveyor. Dr. Waldo said that he had visited every house where fever was present and that he was still investigating the origin of the outbreak. The chief preventive measures taken were: (1) isolation of 89 of the cases in hospital; (2) disinfection and cleansing of premises and of infected goods; (3) accommodation of 25 "contacts," or persons from infected tenements, in the parish reception-house; (4) flushing of the street gullies in the infected area: (5) bacteriological and chemical examination of water, milk, ice-cream, water-ice, and shell-fish; and (6) distribution of leaflets advising householders to refrain from drinking unboiled water or milk and from eating uncooked shell-fish.

Births, Marriages, and Deaths.

BIRTHS.

Haines.—On Oct. 12th, at Brookside, Winfrith Newburgh, Dorchester, Dorsetshire, the wife of Frederick Haselfoot Haines, M.R.C.S., L.R.C.P., D.P.H., of a daughter.

Lillie.—On Oct. 10th, at Fairview, Albert-road, Ashford, Kent, the wife of Cecil Firmin Lillie, M.B., of a son, stillborn.

Murray.—On Oct. 12th, at Dunoran, Renton, Dumbartonshire, the wife of David Murray, M.B., C.M., of a daughter.

Pearson.—On Oct. 6th, at the Crofts, Castletown, Isle of Man, the wife of Ellis Pearson, F.R.C.S. Edin., of a daughter.

Pitcairn.—On Oct. 16th, at Parkhurst-road, Holloway, the wife of John J. Pitcairn, M.R.C.S. and L.R.C.P. of a daughter.

Roberts.—On Oct. 14th, at Clivedon-place, S.W., the wife of Edward A. Roberts, M.D., of a daughter.

Segundo.—On Oct. 15th, at Brook street, Hanover-square, the wife of C. S. de Segundo, M.B., B.S. Lond., of a son.

Vaughan.—On Oct. 10th, at Crewe Cottage, Crewe, the wife of Alfred Ellis Vaughan, L.R.C.P. Edin., of a son.

MARRIAGES.

Hawthorne—Lorimer.—At Marylebone Presbyterian Church, London, W., on the 10th inst., by the Rev. George Hanson, M.A., D.D., Charles Oliver Hawthorne, M.D., M.R.C.P., to Janie Lorimer, M.B., Ch.B., daughter of William Lorimer, Esq., Glasgow.

Oliver—Ledgard.—On the 16th inst., at Holy Trinity Church, Clapham-common, by the Rev. B. Wilson, vicar of Battyeford, cousin of the bride, assisted by the Rev. W. T. Hollins, vicar of St. James, Clapham, George Oliver, M.D., F.R.C.P. Lond., of Harrogate, to Mary, daughter of the late W. Ledgard, of Roundhay, Yorkshire.

Tinley—Lea.—On Oct. 12th, at St. Oswald's, Lythe, Yorks, Thomas Tinley, M.D., J.P., of Hildegard House, Whitby, and the Bungalow, Sandsend, to Annie Mary, elder daughter of Thomas Lea, Abbey-terrace, Whitby.

White—Randle.—On the 11th inst., at St. Andrews, Ashley-gardens, Arthur T. White, M.R.C.S., L.R.C.P., Principal Medical Officer, Nile Reservoir Hospital, Assuan, to Mabel, eldest daughter of the late N. Randle of Bombay and Mrs. Randle, of 25, Morpeth-mansions, Victoria-street, S.W.

DEATHS.

Langdon-Down.—On Friday, 5th Oct., 1900, at Normansfield, of pneumonia, Mary, wife of the late J. L. H. Langdon-Down, M.D., F.R.C.P., J.P., of Normansfield, Hampton Wick, and No. 81, Harley-street, W., in her 72nd year.

Redman.—On Oct. 8th, suddenly, J. H. Redman, L.D.S., of Wimpole-street, London, and Old Steine, Brighton.

Savage.—On Oct. 3rd, at Loudoun-road, N.W., Henry Savage, M.D., F.R.C.S., one of the Founders of the Samaritan Free Hospital, in his 91st year.

Swayne.—On Oct. 12th, at Pembroke-road, Clifton, Bristol, Samuel Henry Swayne, M.R.C.S., L.S.A., aged 79.

Young.—On Oct. 11th, at Melville Lodge, Ventnor, I.W., David Young, M.D., late of Rome, aged 61 years.

In Memoriam.

Mackey.—In memory of my dear husband, Stephen William Mackey, L.R.C.S.I., L.K.Q.C.P.I., L.M., the anniversary of whose death occurs Oct. 24th. R.I.P.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE DRUGGIST AND THE QUACK

We have received a letter from an officer in the Royal Army Medical Corps which we print below with its extraordinary enclosures The letters from Mr A J Paul reveal the fact that he has acted as a quack as much in the interests of an enterprising druggist as in his own Mr Paul's handwriting shows him to be a German, which accounts for the obscurity of his English literary style, but there is no doubt whatever about his vocation He is a dangerous quack, and a druggist who respected his calling would hesitate to assist him in his dangerous work and to make money through his agency

To the Editors of THE LANCET

SIRS,—I send some letters which came to me through the Provost Marshall of this town, as they show how a medical quack in the Transvaal has acted as commercial traveller to a druggist Please do what you think best with the letters

I am, Sirs yours faithfully,

Sept 15th, 1900 LIEUTENANT R A M C

[ENCLOSURES]

p k, Badfontein, *via* Machadodorp
24th of June, 1899

DEAR SIR —Medicines received in good order Thanks for instructions I hope to do a lot of business with you As you see the medicines do very good, and nearly daily I get more to do People dont trust much in Lydenburg doctors I send with next post p o o ad £2 16 0, as I have to send to Lydenburg for it—and the opportunities are very scarce, Badfontein is only a store 2 hours on horse back from here When you send me medicines please send me a/c at the same time I received only one a/c ad £2 15 8, but for the last 4 bottles I did not yet receive one Some times it might happen that I send you a/c a little late, according to occasions to town so I hope that you will not blame me if it happens Please send me by return —

1 For an old woman of 63 Womb comes down *every* morning and then it is very hot—like burning—a few hours after that she is getting alright again

2. For Mrs you sent me medicines for Showed me her breast—(Cra [illegible] erysipelas—so it look [illegible] ce the same (she did [illegible] e is very fat and [illegible] n the last month— [illegible] of the legs—pain under chest, left side—headache—she is very weak She has been sick for about 3 month She is mother of many children.

4 One daughter of 17 About 3 months ago in the time of her monthly discharge she came into cold water—then the sickness disappeared—sometimes does not come in many weeks, since never regularly Pain under chest left side.

5 A man caught a cold when on last commando in October—never got better—pain in his forehead and face and jaw bones He tried Ayers Pectoral—without any good

6 One Mrs about 31—7 years ago when she got last baby—the after birth did not come off well—but not taking notice she walked on She is for a very long time complaining about tooth ache, then the pain goes into her head after that under chest and back I should be pleased if you could give me the best you can find for her also for her teeth, which are hollow She tried all kinds of medicine without results

/ 3 Lung openers

You understand dear Sir that I prefer your own medecines—none of Ayers or Chamberlains Trusting that you will send as s on as possible

I remain, yours sincerely, with kind regards,

A J PAUL.

Please send at the same time a/c P

If I get your a/c to-day at Badfontein then I will make it one order! Last Sunday I drove 3 wurms out of *one* woman I regard that as a curiosity I will have a lot of it to do with those tape wurm bussiness. Kind regards P

No 8 A woman, 39, pain left side under her chest discharge regularly except once She is always very cold, even when it is a hot day She has got a dozen children She is very poor

9 A young man of 20, pain on the bottom of his stomach His life is always open, and he can eat whole day long No wurms Same man wants some to purify his blood.

Yours truly

PAUL.

P K Badfontein via Machadodorp
11 July, 1899

DEAR SIR —Please supply me with friday coach here.

G B—, 56 years —Pain in his bladder, pain under short ribs can hardly piss he remembers kept it up too long dont understand him—I never heard about that He is very painful under his breast, legs, back, etc

F N— 28 years Pain both sides of his breast and between his shoulders After meals he feels dejected Headache

V J— 1½ years—thread wurms

Mrs J C— She got medicines last week—she got a cold—she is getting better, but not recovered yet, she feels pain still, but not as it was before She is that Mrs of 36 No 3

She is very weak. Perhaps wants that tonic High family way

Mr V—, about 63 —I gave him lung opener, he feels better Got a painful place between shoulders about 4 inch diam, he feels little better When he touches his *left* arm *than* at the same time wind comes up out of his mouth any time wherever he touches that arm is painful

Mrs V— 62. I gave her long opener—feels better—gave her pain balm for shoulders—feels better Wants some more medicines for *chest* and pain in the arms from shoulder to fingers I think this is Rheumatisme

If you can manage it to send those medicines on wednesday or thursday morning—than I can have them with friday coach—please enclose your a/c—that I can settle As I wrote—if you want any security—as you dont know me—then I can let you have it, that you need not to be afraid

With kind regards

Yours sincerely

A. J PAUL

p k Badfontein, via Machadodorp,
17 July, 1899.

DEAR SIR —I have been very busy so could not answer one of your letters up till now By opening the parcels at the store I found 2 lung openers broken—it must have happened not far from the store—while on the coach, as all papers and wood wool was wet yet Further all recd in good order Lung opener for Mrs — does not do much good yet She has got that pain in shoulders and awfully headache still I got no more General mixture, otherwise I would have supplied Mrs of 36 is nearly recovered—after doctoring in Lydenburg for three months she got worse and worse your medicines therefore first class About a/c up to £10 Thanks for your confidence I shall regularly settle up Saturday I wired

Send by rail to Machadodorp further by coach 12 Lung openers 12 General Mixtures, 12 Whooping cough Whooping cough broke out Please give me some particulars about children from 5 months to 2 years Same time you might inform me for what kinds of sickness *General mixture Lung openers* and *Toric acid is to be used*

You will please send me a measure-glass and 1 syringe—those thing come in very handy

Is lung opener also good for inflammation of lungs?

Some people (women) are complaining about *darkness* in their eyes What can I do? I suppose it is in connexion with monthly discharge but I am afraid to do anything in this line as an eye is a very weak thing I think you may send me some *oog water* en een klein spuitje om oogen in te spuit At the same time you may let me have my full a/c after all these ordered medicines then I know what to charge

Very wonderful it is that people all come to me after so very good results with Mrs O—, Dr O— in Lydenburg supplied her with medicines and at last they gave it up as she was nearly dying I was very sure that your medicines after my informations would do good—so I took it on me to try my best and the result are *very* wonderful If I know now exactly, *according* to *ages* how to supply the *doses* I am well informed and can make some money out of it Lung openers as last sent are very good

With kind regards and trusting to receive all particulars about whooping cough medicines how to mix, etc

I remain, with most respects yours sincerely,

A. J PAUL.

SECRET COMMISSIONS AND THE MEDICAL PROFESSION

To the Editors of THE LANCET

SIRS —We sincerely thank you for calling attention to the circular marked "private" which was issued by us in reference to our project for visiting the thermal springs of New Zealand On Sept. 27th last our attention was called to the breach of professional etiquette committed by us when the offending circular was at once withdrawn and cancelled the precise number issued being only 32, and these were sent to specialists of high repute only Please note the class of cases proposed to be treated, and that in the interests of all we propose to take charge of such patients only who are not likely to require medical aid other than can be obtained during the voyage and for the purpose of determining this we may require in the interests of the patients themselves in cases of doubt the assistance of medical men We quote the following paragraph from the New Zealand Steam Shipping Company's Monthly Circular as it explains the service required and intended to be covered by the "secret commissions" referred to "The Company reserve the right of refusing to carry any passenger who may be mentally or physically afflicted and who must on booking state the nature of any infirmity Any passenger suffering from infectious disease will not be permitted to embark." The so-called "secret commissions" were intended to cover fees for assistance in this direction and in no way to act as a bribe or bring corrupt influences to bear, which would, indeed be a very tall order. All our arrangements are based on the assistance of only qualified medical men and their assistants. In the meantime we shall be glad if you will give the same prominence to this rejoinder as you have given to your attack upon our venture and oblige.

We are, Sirs, yours faithfully,
J. BASTOW AND SON.
Woodbine Villa, Earlsfield-road, Wandsworth-common, S.W.,
Oct. 13th, 1900.

"MOTOR-CARS FOR MEDICAL MEN."

To the Editors of THE LANCET.

SIRS,—Your correspondents upon this subject seem to be decidedly depressed. I should prescribe a good run on a good car or trike for them both. Mr. Hirsch takes a gloomy view of cars in general, apparently because he has had rather a rough time with his own in particular. Does not your other correspondent give himself away when he confesses that he judges the capabilities of autocars by the number he sees in dock? Would it be equally fair to say that humanity is diseased because a hospital was full? Admittedly cars break down, just as horses fall, kick, shy, bolt, and smash up traps. Perfection is not yet attained in anything, not even in our profession, but we do not therefore withhold our help because we cannot guarantee a cure. I began, an absolute novice, to use a motor trike last January in miserable weather and very unfavourable conditions. It gave me no trouble, cost next to nothing to run, and so far from making me late made my work seem very light and easy. This is the other side of the question.

I am, Sirs, yours faithfully,
CLAUDE A. P. TRUMAN,
Honorary Secretary, Reading Automobile Club.
Reading, Oct. 15th, 1900.

To the Editors of THE LANCET.

SIRS,—Several letters have lately appeared in your correspondence columns on the above subject. Let me say, as one who has a general knowledge of all the best known makes, that in my opinion no motor-car has yet appeared that can be said to be in every way suitable for the use of medical men—up to the present they are all too intricate. What a medical man wants in a motor is one that can be as easily controlled and managed in going from house to house as an ordinary horse and trap and not one made for speed, and I may say that one of this description will shortly be on the market—a motor moderate in price, comfortable, reliable, simple in construction, without belts, chains, or chain wheels, and capable of being understood at once, thus doing away with the necessity of having a skilled driver. Your readers may expect an announcement of this in your advertising columns shortly. I am, Sirs, yours faithfully,

Oct. 15th, 1900. MOTIST.

To the Editors of THE LANCET.

SIRS,—I have noticed with regret the letters on this subject in your paper. My experience is fortunately quite different. I have had a small car two years. In this time I have had no trouble whatever with the engine; my only worries have been tyres, chains, and wheels, &c. The car has carried me about 11,000 miles over all roads and in all weathers, including two tours, and is still going splendidly. This week I have travelled over 200 miles easily in my work The car does the work of more than two horses. It costs me altogether between £30 and £40 a year, which is certainly much cheaper than two horses and infinitely less trouble and worry. Another advantage is the speed. I can keep up a good 10 miles an hour up hill and down dale, or 12 or more miles an hour on the level, which is an immense saving of time and consequently of money. In my experience of country work a motor is a brilliant success. The only point is that one must understand the engine and take care of it, and the chains, &c, and it will repay one. For pleasure nothing can surpass it, and automobilism is a most fascinating amusement.

I am, Sirs, yours faithfully,
Oct. 17th, 1900. BENZ CAR.

A QUESTION OF BOYCOTT.

THE writer of a letter, asking if a medical man should be boycotted because of the circumstances under which he resides in a certain house, has omitted to give us his name and address.

THE PROSPECTS OF THE NEWLY-QUALIFIED MEDICAL STUDENT.

To the Editors of THE LANCET.

SIRS,—At the distribution of prizes to the successful students of St. Thomas's Hospital on Oct. 2nd Sir William Mac Cormac stated that in his opinion the present time was most favourable for entering the profession with the assurance of earning a competency; he also stated that the average increase of medical men was 450 during the last three years and 845, or nearly double the number, during the five previous years. Mr. Stansfield Collier, on the other hand, in his introductory address to the students of St. Mary's Hospital, said ..... "from the point of view of a livelihood—aye, there's the rub."

An eminent consultant like Sir William Mac Cormac cannot have the experience of a general practitioner in such matters. When one considers the large number of patients who would have paid the medical attendant a reasonable bill but who now are members of medical aid and benefit clubs, provident dispensaries, or attending the out-patient departments of special or general hospitals, the outlook is certainly anything but a bright one. The medical schools advertise largely, scholarships are offered to attract the student It is natural enough for the staff to wish their own particular school to be a success, they therefore try to get a good entry. When we consider that the staff consists mainly of men in consulting practice who, with few exceptions, know little, and in many cases care less, about the general practitioner's struggle for existence, and are mostly brought into contact with the successful practitioner but do not meet or hear of the unfortunate man buried in a slum or forced to keep a sixpenny dispensary, of what value is the consultant's opinion? The late Sir James Paget's figures of 276 failures in 1100 medical men kept under observation for a period of 16 years do not sound encouraging. What would the number of failures be at the present time? Has Sir William Mac Cormac any idea of the number of young and middle-aged medical men trying to buy practices or settle down in likely town or country districts? As house surgeon to a provincial hospital for many years I was often consulted by medical men who were thinking of starting practice in the neighbourhood. The cry of many was this: "I have enough money to buy a practice, or a share in a practice, but have wandered about the country during the past two years (often more), and although I can get a few locums and assistantships I have been quite unable to find any suitable opening." The unfortunate medical man with money to buy a practice finds things bad enough, but woe to the man without any.

I am, Sirs, yours faithfully,
Oct. 16th, 1900. G. P.

THE SPAS OF CENTRAL WALES.

To the Editors of THE LANCET.

SIRS,—After spending a very pleasant holiday at Llandrindod Wells I would, with your permission, make a suggestion to the Balneological Society that they should imitate their French *confrères* and organise trips to the various inland watering-places during the month either of August or September. Although I am fairly acquainted with most of the inland watering-places I must honestly confess that for beauty of scenery and for exhilarating air the neighbourhood I have mentioned stands very high in the list. I say nothing about the waters because I am not competent to do so.

I am, Sirs, yours faithfully,
Cardiff, Oct. 13th, 1900. T. GARRETT HORDER.

"A NEW WOOD FOR STREET PAVING."

WITH reference to the note on this subject which appeared in our issue of Oct. 13th Mr. E. M. Allcott, the introducer of the wood in question, writes to us to say that the wood "is treated in its natural state, no acids or chemicals being used whatever." He also sends us a copy of a portion of a report of some experiments made by Mr. Weaver, surveyor to the Kensington Vestry. Mr. Weaver found that the red gum wood placed under pressure in a creasoting tank absorbed "practically none at all," whereas deal absorbed "10lb of creasote to the cubic foot." This non-absorbent quality is certainly valuable from a sanitary point of view.

THE REMOVAL OF SUPERFLUOUS HAIRS.

To the Editors of THE LANCET.

SIRS,—I hope some of your readers who have tried removing superfluous hairs from the face will give me the benefit of their experience. I have a patient, a girl, who besides being very short has a well-marked moustache. These factors, especially the latter, make her very shy and morbid, and I feel that if she could have the hairs removed she would be much improved in health.

I am, Sirs, yours faithfully,
Oct. 10th, 1900. BATH.

*** Our correspondent is referred to THE LANCET, vol. i, 1899, pp. 1202, 1271, 1340, 1408, and 1468.—ED. L.

YORKSHIRE SANITARY INSPECTORS' ASSOCIATION.

THE annual meeting of this association took place at the Council Hall, Rotherham, on Saturday, Oct 1st, 1900, where Mr. T. Pridgin Teale presided. Mr. Teale was re-elected president and Mr. Evington, as chairman of the branch council, gave an address in which he mentioned that the association had over 600 members, 100 of whom belonged to Yorkshire. Dr. Alfred Robinson, medical officer of health for Rotherham, then read a paper on the Gain to the Community through the Adoption of Effective Measures against the Spread of Infection.

◆

Pathology (Wigan) would be glad to have references to a case or cases of ambulatory typhoid fever in which the patient was able to eat, sleep, and do laborious work, in fact, was apparently in good health, up to 60 hours before death. "Pathology" has references to cases of perforation reported in THE LANCET, vol. ii., 1870; vol. i. and vol. ii., 1873; and vol. ii, 1881.

A. J. P.—The work in question was an account of a suggested system for universal language.

ERRATUM.—In our last issue at page 1081, col. i., line 32 and 33, *Nigeria* should be read for "British New Guinea."

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

ABSTRACT OF

The Harveian Oration

ON

THE FORCES OPPOSED TO HARVEY AND HIS RESEARCHES.

Delivered before the Royal College of Physicians of London on Oct. 18th, 1900,

BY T. CLIFFORD ALLBUTT, M.D.,
F.R.C.P. LOND., F.R.S.,
REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE.

MR. PRESIDENT AND GENTLEMEN,—The discovery of the circulation of the blood by William Harvey is commonly regarded among scientific discoveries as eminent if not unique, and this in the judgment not of Englishmen only. My purpose to-day is to show that at any rate it was made against enormous difficulties.

To put this discovery in right perspective we must have some vision of the history of philosophy, science, and medicine. Medicine, herein in contrast with theology and law, had its sources almost wholly in the Greeks; from them for good or evil it took its first scheme of thought; and in the schools of Hippocrates and of Alexandria it was based, more soundly, on natural history and anatomy. The noble figure of Galen, the first physiologist and the last of the great Greek physicians, portrayed for us by Dr. J. F. Payne in the Harveian Oration of 1896, stood eminent upon the brow of the abyss when, as if by some convulsion of nature, medicine was overwhelmed for 15 centuries. Galen practised the method of verification by experiment, first introduced, perhaps, by Archimedes; but after him it was lost till the time of Gilbert, Galileo, and Harvey.

In the growth of societies small civilisations have been sacrificed to the formation of larger aggregates, whereby stable equilibrium may be attained for the highest ends. Perhaps because of her very freedom of thought Greece never became a nation. Even the Roman peace, bought as it w [illegible] but a mechanic [illegible] the bodies but [illegible] even in Rome [illegible] Under the Fra [illegible] and obedience [illegible] saved by the [illegible] entering as a new element into the ancient fabric of Roman empire, was now to hold men's service in heart and soul as well as in body; but to this end no mere mystic or personal religion could suffice; clothing itself with the political and ritual pride and even with the mythology of the pagan empire it inspired a new adoration, but it imposed upon men also a universal and elaborated creed. In the third century philosophy was born again in neo-platonism, the offspring of the coition of east and west in Alexandria, where all religions and all philosophies met. The world and the flesh were crucified that by the spirit man might enter into God. Pure in its ethical mood, neo-platonism, says Harnack, led surely to intellectual bankruptcy; the irruption of the barbarians was not altogether the cause of the eclipse of natural knowledge. Yet even then, as again and again, the genius of Aristotle came to save the human mind. Proclus, ascetic as he was, was also versed in *Aristotle* and he compelled the Eastern mysteries into peripatetic categories and bequeathed a formal philosophy to the Faith. Thus the first scholastic period was fashioned and the objects and methods of inquiry were determined for 30 generations. Rationalised dogma lived upon dialectic and conflicted with mysticism, but logic, dogma, and mysticism alike disdained experience. The Faith then was the first adversary of Copernicus, Galileo, and Harvey.

[illegible] Faith that of all the treatises of [illegible] fantastic and least scientific, [illegible] ct the mediæval world, while [illegible] knowledge fell out of men's han [illegible] and the "Interpretation" mad [illegible] nominalism and turned men's minds rather to rhetoric and dialectic than to natural science. Thus it was that Plato's chimæra of the human microcosm, a reflection of his theory of the macrocos [illegible] adversary of ph [illegible] by Europe was [illegible] human ideas. [illegible] so was that of I [illegible] Ages of the Arabian versions of Aristotle and Galen. It is not easy for us to realise a time when intellectual progress, which involves the successive abandonment of provisional syntheses, was unconceived, when truths were regarded as absolute, when reasons were not tested but counted, when even Averroists found final answers either in Aristotle or in Galen. Thus in the irony of things was Harvey withstood by the dogma of that Galen who, in his own day, had earnestly appealed from dogma to nature.

In the *Isagoge* of [illegible] problem which during [illegible] asunder, a problem, say [illegible] more of the time and passions of men than for the house of Cæsar to conquer and govern the world; a problem, indeed, which in our own day is not wholly resolved. This was the controversy of the Realists and the Nominalists, first brought to a clear issue by William of Champeaux and Roscellinus. Now Plato held ideas not as mere abstractions but as creative forces, and we shall see how potent was this function in mediæval thought. Every particular, every thing, was regarded by the realist as the product of universal matter and individual form. Now form might be regarded, and variously was regarded, as a shaping, determinative force or principle, pattern or mould, having a real existence apart from stuff; or, on the other hand, as a principle or pattern having no existence but as a conception of the mind of the observer. And for the Realist not individuals only but genera and species also have their forms, either pre-existent (*universalia ante rem*) or continuously evolved in the several acts of creation (*universalia in re*). For instance, the Church exists for the Realist as a thing apart from the wills of successive generations of individual men; man has fallen not only in many or all individual cases but also as a kind—a kind having an independent existence; in the Sacraments, again, there may be a change of hypostasis without change in sensible matter. Now if forms pre-exist (*ante rem*) the Will of God must be pre-determined; or if form be an immanent function acting *in re* we are landed in Pantheism. Thus Erigena, the brilliant prophet and Protestant of the first period of the scholastic philosophy, was virtually a Pantheist, as Spinoza was the last great Realist. Aquinas, who determined the philosophy now ruling in Rome, brought about a compromise which covers up rather than solves the difficulty. The problem, it is evident, was no hair-splitting; it dealt with the very nature and origin of being and it agitated the minds of earnest men at a time of fervid and widespread enthus [illegible]

Now closely allied to the [illegible] was that concerning "mat [illegible] terms used were "form and matter," "force, energy, or pneuma and matter," "soul, archæus, or life and body," "determinative essen [illegible]" "male principle and f [illegible] clay of the potter"; or [illegible] cause," "nature and law," "being and becoming," the riddle lay in the contrast of the static and dynamic aspects of things; in the incessant formation of variable individuals in the eternal ocean of existence. Even Francis Bacon never got out of the tangle of form, cause and law. It has been the temptation of philosophers of all times, and even of Harvey himself, than whom none had put better the conditions of scientific method, to suppose that by means of abstraction kinds may be apprehended; that thus they may get nearer to the inmost core of things; that by purging away the characters of individuals they may detect the essence and the cause of individuation, not perceiving that the content of notions is indeed in inverse proportion to their universality. We see this error continually to-day; for instance, we may discuss the causes of typhoid fever and bewilder ourselves by forgetting that there is no such thing as typhoid fever, and that the only causes of a general notion are the psychological *causes of its generation in the* mind of the thinker at the time; that which is due to objective causes is of course not the general notion but the particular case, a very different matter.

Before motionless stuff—before the problem of the "primum mobile"—even Harvey himself stood helpless when he had come to the end of his admirable experiments and began to indulge in contemplation. In his need for a motor for his machine he was not able to divest himself of the language or even of the philosophy of his day. In his day he could not help regarding rest and motion as different things and motion as a superadded quality. The motion he attributed not to a property of the heart but of the blood—to its "innate heat," which is as far as he could possibly have got. But by way of explanation he adds that the innate heat of the blood is not fire nor derived from fire; nor is the blood occupied by a spirit, but is a spirit; it is also "celestial in nature, the soul, that which answers to the essence of the stars ...... is something analogous to heaven, the instrument of heaven." In denying that a spirit descends and stows itself in the blood or elsewhere, as an "extraneous inmate," he bravely says: "I cannot discover this spirit with my senses, nor any seat of it." And yet in the treatise "De Generatione" he propounds a theory of the impregnation of the female not by any material from the male but by the influence upon her of a "general immaterial idea," which even for his own time was very substantial realism. The riddle which oppressed the great thinkers from the Greeks to Lavoisier was then the nature of the "Bildungstrieb"—of the "*impetum faciens*." What makes the ball to roll? Does heart move blood or blood move heart, and in either case what bestows and perpetuates the motion? Telesius, the first of the brilliant band of natural philosophers in Italy of the sixteenth and seventeenth centuries, still sought this principle of nature in the "form" of the peripatetics. Gilbert regarded his magnetic force as "of the nature of soul, surpassing the soul of man." Galileo, although willing to conceive circular motion as perpetual and even self-existent, was unable thus to conceive rectilineal motion. All these naturalists, including Harvey and even Descartes, followed the mediæval world and Aristotle in deriving the source of motion directly from that of the spheres—from the quintessence.[1] Till Copernicus transfigured the cosmos, and Galileo and Newton carried terrestrial physics into the celestial worlds, the heavenly bodies were regarded as animated beings, themselves active, and by propagation from sphere to sphere animating all "sublunary" matter, wheels within wheels, even to its innermost particles.

Of the origin of energy we have not solved the riddle—we have given it up; but instead of finding its sources without we find them within. Harvey's contemporary Francis Bacon sagaciously guessed that heat is an expansive motion of particles, but he regarded heat and cold as two contrary principles. Almost in the same generation the brilliant John Mayow perceived a substance in the air "allied to saltpetre" which passed in and out of the blood by the way of the lungs or placenta. So innate heat gave way to phlogiston, and soon afterwards oxygen and the conservation of energy turned out to be "form," "spirit," "essence," "primum mobile," "causa efficiens," "potentiality," and the rest of them, and by Lavoisier a vast pile of metaphysics was blown into the air. But to kill a strong theory outright takes many a generation. Realism, shaken by Abelard and scotched by Hales and Ockham, not only survived to mislead Harvey, but it stretches its withered hand over us still, in the nursery, in the schoolroom, in the university, and in the great arguments of life.

As strong as realism was a third adversity—the pride of human mind. The asceticism of the East, disdainful of carnal things, brought the dualism of matter and spirit into monstrous eminence; and in respect of medicine in a few generations it turned the cleanest people in the world into the most filthy.[2] Almost to this day the mechanical arts, presumably concerned with lower categories, have been regarded as base, and the crafts, even of the laboratory, as unworthy of great souls. Anatomy had to labour also against both ecclesiastical and popular antipathy; chemistry and mechanics were gross pursuits unless endowed with the perilous distinction of alchemy and sorcery. Unfortunately, this charge upon the dignity of man was made heavier rather than lighter by Petrarch and the humanists of the Renascence; and in Oxford of the seventeenth century we find that Boyle was bantered by his friends as one "given up to base and mechanical pursuits." In a certain important respect medicine suffered greatly from this prejudice. It is obvious that, speaking generally, medicine would find its most positive and direct control in those diseases and in those therapeutical experiments which take place on the outside of the body. Yet surgery fell under the proscription of a handicraft, and, as such, was eliminated from the College of Physicians both in London and Paris; and thus the genuine work of such men as Paré and Gale was without influence upon medicine. Thus it came about that Francis Bacon says of the physicians of Harvey's day that they saw things from afar off as if from a high tower. From Erasistratus to Celsus physicians practised medicine as one art. Galen taught not the simplicity but the unity of medicine; and Littré points out that this unity is consistent in the Hippocratic writings. Surgery, by virtue of its imperative methods, was kept clear of philosophy on the one hand and of humanism on the other. Fortunately for Harvey his master Fabricius was as great a surgeon as anatomist; and such also was Fallopius. Thus it was that medicine at the end of the Middle Ages had not recovered the standard of Alexandria. And against this adversity also had the founder of physiology to contend.

Happily, Arabian scholastic philosophy took its root in Alexandria when neo-platonism had veered towards Aristotle and was therefore more uniformly peripatetic than the Christian scholasticism. It is one of the signs of the greatness of Aristotle that thus garbled and glossed his power made itself felt in the thirteenth century, chiefly by the great Franciscans Alexander Hales, Roger Bacon, and William Ockham—Roger Bacon whom we may call the first of the natural philosophers of the West. This former renascence determined the second period of the Middle Ages, the period distinguished by the Arabian version of Aristotle, by a check to the chimæras of realism, by some liberty of secular knowledge—for even bishops came out of the school of Toledo—and again by the coming of the friars whose influence upon the thought of the Middle Ages was a curious proof that as all ways are said to lead to Rome, so all systems of thought, in spite of the thinkers, led to natural science. The logic and rhetoric of the Dominicans, by their rationalism, defined, and in defining restricted, the dominion of the Faith. Men got used to reason and made a language for thought. And in the history of the unlearned Friars Minors we find, as elsewhere in history, that mysticism is more favourable to natural knowledge than the passionate dogmatism of Clairvaux or the dogmatic rationalism of St. Thomas. The Victorians, as Gerson after them, despised reason rather than feared it. Mysticism makes for individual religion, as in Glisson and Newton, rather than for the Church. Hence it may have been that independent thinkers, like Hales and Bacon and Ockham, entered the Franciscan order. The former renascence brought also a more tolerant spirit. Albert of Cologne owed as much to Avicenna as St. Thomas to Averroes—sages technically damnable, yet "mighty spirits" worthy of reverence. Dante put in hell, but on green meadows in an open place, lofty and luminous, not only Aristotle, Plato, and Socrates, but also Euclid, Ptolemy, Hippocrates, Avicenna, Galen, and "Averroes, who made the great commentary." Universities were founded in France, England, and Italy. But the natural science which made the second renascence irresistible was absent from the former and at the end of the century a reaction set in. During the two following centuries in Spain freedom of thought was crushed out by the Church; but in the conflagration of books of philosophy medical works, such as the "Colliget" and the Commentary on Galen of Averroes, were largely spared; yet in the fourteenth and fifteenth centuries the very name of Averroes, "the mad dog that barked against the Christ," not only became ecclesiastically accursed, but also began to signify loose life as well as free thought; a resentment of which there was no trace in Albert or Aquinas.

Averroism, however, held its ground at Padua, which had become celebrated for medicine as Bologna for law, and although Averroism, like any other philosophy taught as a separate study, decayed, yet, effete as it was, it kept the ground open at a time when the tide was turning against free thought, when the commercial supremacy of Venice was declining, when the Spanish Inquisition was established in Rome, and when even the influence of the Florentine humanist was rather against natural knowledge than for it. No doubt the coarse and disingenuous scepticism of the physicians of North Italy and their pretentious manners alienated the humanists not only from themselves but also

---

[1] Vide Arist., De Coelo; and Met. xii.

[2] Those curious in such things will notice that the mediævalising clergy of our own day have discarded in their persons that fair linen which in their fathers was the emblem and example of cleanliness.

[illegible] such as Telesius and Galileo; and alike stood by at the burning of Padua at a fortunate time; he found Galileo engaged in teaching and also in methodical research, for Galileo was not only a great discoverer, but he was the first to formulate fully and clearly that method which we know under the name of the "inductive method." The discovery of Greek texts had destroyed the conventional Aristotle and the conventional Galen; Gregory by the reform of the calendar had put the axe to the root of astrology; Newton was soon to carry terrestrial physics into celestial spheres; and Boyle was soon to create chemistry; anatomy was fully awake already. In England, moreover, with the accession of Elizabeth more spacious times were assured, and Charles protected Harvey. Clinical teaching also had been established at Padua by Fracastorius and Montanus, to be pursued in Heidelberg, Leyden, and Vienna Physiology, however, was awaiting Harvey. Servetus had buried his conception of the lesser circulation under a pile of theology; Columbo and Fabricius, however, had prepared the way, not so much by the value of their discoveries as by their practice of the experimental method in this science, for the anatomists, Galenists to a man, had done next to nothing for physiology.

The genius and courage required to make discoveries like that of the circulation of the blood, cannot be measured directly; there is no method of determining the specific gravity of such adventures: I have tried, however, to shadow forth the weight of the social systems, opinions, prejudices, and habits against which Harvey's gigantic effort was made. Almost in the year of the publication of the "De Motu Cordis" (A.D. 1628) the Parliament of Paris issued an edict that no teacher shall promulgate anything contrary to the accepted doctrines of the ancients. Under such conventions Harvey's discovery burst like an earthquake—under *corrupt Galenism, venerable sophistries, current abstractions* bequeathed by realism, and long-winded dialectics on critical days, coctions, derivatives, or revulsives, and dogmas based on uncritical subservience to texts His work stood out even more ascendant against a lurid background of folk superstitions—of vampires, witch-burning, magic, cabbalism, astrology, alchemy, chiromancy, and water-casting. In terrestrial and celestial physics Galileo, persecuted as he was, had some strong current with him; Copernicus was before him, Kepler was beside him; but in physiology upon the path of Galen the waters had closed as upon the track of a great ship; and among Harvey's contemporaries and immediate forerunners there was none to claim a share with him in the discovery of the central fact of physiology, or in his application of the method which opened the way to Pecquet, Glisson, Steno, Wharton, Willis, Haller, and Bernard.

An Address
ON
APPENDICITIS.

Delivered before the Mirfield Medico-Chirurgical Society.

BY HARRY LITTLEWOOD, F.R.C.S. ENG.,

SURGEON TO THE LEEDS GENERAL INFIRMARY AND LECTURER ON PRACTICAL AND OPERATIVE SURGERY IN THE YORKSHIRE COLLEGE (VICTORIA UNIVERSITY)

GENTLEMEN,—I very much appreciate the kindness which prompted the members of this society to ask me to be here this evening, and I felt that I had only one course open to me and that was to accept your kind invitation.

The subject which I have selected to bring before you is appendicitis. I am afraid, however, that I can tell you very little which you do not already know or which you cannot find in the numerous monographs on this subject that have been written during the past 10 or 15 years. Still, I have thought that to hear how the subject is viewed by one who, like myself, enjoys the privilege of being attached to the full surgical staff of a great provincial hospital may be of interest, and perhaps of some value, in helping you in the diagnosis and treatment of cases of this nature which may present themselves in your practice. To bring one's thoughts to a focus from time to time as to the pathology of any class of disease, or to review any portion of one's work—the mistakes and failures as well as the successes—is always a useful and wholesome discipline. We see where we stand and [illegible] we have yet to overcome in p[illegible] and treatment. To no class [illegible] to members of our profession and that, I think, is one of the great functions of our medical societies We are so accustomed to give dogmatic opinions to our patients that if we had not the restraining influence of the friendly criticism of our *confrères* we should be in danger of believing our own dogmas and cease to have an open mind, receptive for the new developments of an ever advancing knowledge.

The whole subject of appendicitis is of recent development—15 or at most 20 years—and it is only during this period that the important part played by disease of the vermiform appendix has been appreciated. Here and there a few observers had pointed out the fact that the appendix was diseased and perforated in some fatal cases of peritonitis. In 1812 an English physician, Dr Parkinson, brought before the Royal Medical and Chirurgical Society of London a case of ulcerated and perforated vermiform appendix from a boy, aged five years, who had died from general peritonitis, and it is of interest to us in Yorkshire to recall the fact that in 1861 the late Mr. Nunneley of Leeds described such a case in the Transactions of the Pathological Society of London. Mr. Darwin has not overlooked the condition and refers to it in his "Descent of Man," which was published in 1874. Up to the last few years isolated cases may be found by the careful and patient student scattered throughout medical [illegible] played by the [illegible] its neighbour[illegible] *cæcum, and we* [illegible] is," and "paratyphlitis" to describe the condition. These expressions have now been practically superseded by the term "appendicitis," a word which most of us object to, but which is now so universally in use as to have become a permanent fixture in our nomenclature A recent writer has suggested the term "epi-typhlitis," but I very much doubt if he will succeed in popularising it. Pathologists, making post-mortem examinations with the fixed idea that the disease was in the cæcum, did not upset the views of the orthodox by examining and inquiring into the condition of the appendix. To many observers—workers in America, on the continent, and in this country—we owe our present knowledge. [The anatomy, the variations of position, and the histology of the appendix were described and illustrated by drawings and specimens. One interesting specimen was shown in which the appendix was found in the sac of a right inguinal hernia attached to an [illegible] malignant. The herni[illegible] tion of castration, and [illegible] the testis it was removed.]

Having briefly reviewed the anatomy and histology of the appendix let us inquire into the common causes producing the inflammatory changes. It is more than probable that the presence of scybalous masses or concretions in the appendix is the starting point of a very large proportion of inflammatory processes. By some it has been assumed that these masses are formed in the appendix—and this may be so in a few cases, especially in a long appendix—but it is more than probable that in the majority of cases they are formed in the cæcum The inflammatory changes are probably produced in this way. The concretion enters the appendix and, being large for the lumen, dilates its walls, and by preventing the return of blood produces a venous stasis, or it may simply produce a certain amount of local irritation and perhaps an abrasion of the mucous membrane, and thus a lowering of the vitality of the parts. Micro-organisms, the second factor, now come into play. These are always present in the gut and they attack its walls the moment its vitality is lowered or its walls are injured. A great variety of micro-organisms are present in the gut. The bacillus coli communis and various forms of streptococci [illegible] emoved and the [illegible] acute and acute [illegible] onged, so that in [illegible] ends beyond the [illegible] may form or the whole appendix may become gangrenous. There is some analogy between this condition and the condition produced in a knuckle of gut in a strangulated hernia, but in this instance the constriction is outside the gut, producing the venous stasis and so lowering the vitality of the walls of the bowel. The micro-organisms at once seize their opportunity and may either produce gangrene or some milder form of inflammatory change, for in the fluids found in the sacs of strangulated herniæ micro organisms are invariably present and have in all probability come from the bowel. About a year ago I operated on a case of strangulated femoral hernia in which this condition was beautifully demonstrated. On opening the hernial sac about half an ounce of stinking pus escaped, and after wiping this away a knuckle of gut with a portion of infiltrated omentum was found, these structures forming one wall of the abscess and preventing infection from spreading to the peritoneal cavity. The gut was covered by a white purulent membrane. After thoroughly wiping out the sac I was able to detach the membrane from the bowel; this left a deeply, congested surface which was roughened and bled from two or three points. After having rendered the parts antiseptic I ventured to relieve the strangulation and to return the parts into the abdomen. The patient made a good recovery. Here, I take it, is a demonstration of almost an exact counterpart of what takes place in cases of inflammation of the appendix. In the case of the hernia, had the strangulation been a little more complete or had the operation been delayed a little longer gangrene would have been produced. There can be no doubt that the pyogenic organisms came from the intestine. If you damage any portion of the intestinal wall the micro-organisms are soon at work and may produce any gradation of inflammatory change, ulceration, and even gangrene of the bowel. Two years ago I had a child under my care who had been run over, the wheel of a cart passing over the abdomen. On opening the abdomen about 60 hours after the accident we found a gangrenous patch of the small intestine opposite the mesenteric attachment about two inches long and two-thirds of an inch wide. Round about this was a certain amount of peritonitis, which had been obviously produced by the organisms having gained access by the damaged bowel to the peritoneum. The bowel was stitched to the surface around the gangrenous patch, which separated and left a fistula. The child died after a second attempt to close the intestinal fistula.

Other causes producing appendicitis are foreign bodies in the appendix—e.g., pins, needles, fish-bones, fruit-stones, shot, &c. I removed a specimen some time during last year from a man aged 20 years. The exciting cause was a large needle. The patient made a good recovery. Other causes are kinking and twisting of the appendix; I have removed several which illustrate this point. Amongst the general diseases tubercle may be mentioned. It is sometimes found in the cæcum, but it is rare to find tuberculous disease of the appendix. Typhoid ulceration, malignant disease, and actinomycosis are amongst the rare causes. Gout, rheumatism, and cold are said sometimes to be causes, and the disease may be simulated by hysterical patients The ascaris lumbricoides is said to have been an exciting cause. In two cases of suppurative appendicitis associated with large abscesses which I have operated on some days after the operation ascarides were passed through the opening. The disease is said to be more common in males than in females in the proportion of 78 to 22, and more common in the summer months.

I.—SIMPLE APPENDICITIS (NON-SUPPURATIVE).

The first class, simple appendicitis—the catarrhal appendicitis of the Americans—may be (1) acute or (2) chronic (recurrent or relapsing appendicitis) Here probably the inflammation is confined to the appendix. The inflammatory processes, starting in the mucous or sub mucous tissues, rapidly spread so that in about 48 hours there would be some roughening of its peritoneal covering. The appendix becomes increased in size and it appears turgid and distended. Operations have been performed within two or three days of the onset and this condition has been observed. If the attack subsides the inflammatory materials become absorbed and if the parts are examined a short time after the attack it is quite possible that no evidence of such an attack could be found. In the same way, if the tonsils are examined after an attack of acute tonsillitis nothing may be seen to suggest that the tonsils have been inflamed. If these attacks are often repeated or the disease assumes a chronic form, then definite permanent changes will be found—thickening of the appendicular walls, adhesions to surrounding parts, and partial or complete obliteration of the appendix. It is this condition which is responsible for some of the attacks of relapsing appendicitis. In this class the patients suffer from acute and sub-acute attacks, at intervals varying from a few weeks or months, and in the meantime rarely feel quite well. There is always a little tenderness or something to remind them that they must be careful, a consciousness of something in the right iliac fossa. Some of these patients become chronic invalids. It is important to operate on these patients between the attacks if possible. This condition is often associated with twisting and adhesion of the appendix, the results of several attacks of either acute or chronic simple appendicitis; in some of these cases there has been suppurative appendicitis, the abscess probably becoming encysted and the contents dried up. A fresh irritation arises, to be again lighted up into an acute inflammatory attack.

In some of the cases very little may be found at the operation. I removed a specimen about a year ago from a young lady, aged 23 years, who was under the care of Dr. O. E. Salter of Scarborough, who helped me at the operation, Dr. Geoffrey Thompson kindly giving the anæsthetic. There were no adhesions. The appendix was full of a softish concretion and the walls appeared turgid and inflamed so that it looked very like the erect penis of a child. This patient had had two definite attacks of appendicitis, one in May, 1897, and another in May, 1898. During both attacks she was in bed for about six weeks. Since the last attack she had never been quite well, always having some pain and tenderness in the appendicular region. The patient made a good recovery and since the operation she has been quite well. I have other specimens of relapsing appendicitis all successfully removed, and it is a successful, although at times a difficult, operation. According to Ewald at least 90 per cent. of these cases clear up and the question of surgical interference need never be entertained. My own impression is that the percentage is a great deal lower, and I do feel that there is scarcely ever a case of appendicitis in which those in charge may not have to consider the advisability of operative interference.

There are other simple varieties in which a coagulable exudation (yellowish translucent lymph) may be found extending for a considerable distance around the appendix and cæcum and forming a very definite tumour.

II.—SUPPURATIVE APPENDICITIS.

I will now consider the suppurative cases. In this condition the contents of the appendicular canal are either purulent or muco purulent, the walls are infiltrated with a purulent exudation, and at one or more places the appendix may have perforated. In most of these cases the pus is shut off from the general peritoneal cavity by adhesions and the quantity of pus may vary from a few drops to several ounces. If the inflamed appendix is lying on the external iliac vein or artery in rare cases these have become perforated. If it is in contact with the anterior abdominal wall an abscess may form here, and if it is not operated upon it may burst and discharge itself. In some cases the inflamed appendix may become adherent to the peritoneum; covering the iliac fascia, it may ulcerate through the fascia and an abscess may form beneath it, the inflammation extending into the cellular planes and producing a large tumour by the widespread cellulitis, reminding one of large inflammatory swellings about the lower jaw secondary to a decayed tooth. The whole of this condition may subside, leaving a small encysted abscess. About a year ago (on March 6th, 1899) I operated on such a case.

A woman aged 35 years, whom I saw with Dr. W. H. Holliday of Gildersome, had an attack of appendicitis in October, 1898. She kept her bed for three or four weeks and was away from work for another fortnight. At the time of the attack there was a large swelling in the right iliac fossa extending up into the lumbar region. I think it was one of the largest swellings I have ever seen. The swelling subsided and she felt comparatively well, getting up and performing her household duties. A second attack commenced on Jan. 7th, 1899. There was a good deal of pain, but this time there was practically no swelling. During this attack she had a relapse and after that made a good recovery. At the time of the operation no swelling could be felt, there was just one tender place in the iliac fossa. At the operation I found the appendix acutely bent on itself, and the apex of the bend attached to the peritoneum covering the iliac fascia. In separating the adhesions the free end of the appendix was torn off and it was found that there was a perforation the edges of which were adherent to an opening in the peritoneum and the iliac fascia. This opening led to an abscess extending upwards beneath the fascia and containing about a drachm of inspissated non-offensive pus. This was carefully scraped out and cleansed and some iodoform was put in the cavity, the appendix was removed, and the abdomen was closed. The patient made a good recovery.

When the appendix is situated behind the cæcum an abscess may form and discharge itself into the cæcum. By some this is supposed to be a very common method of spontaneous cure. I have had an opportunity of seeing this condition in a case which I operated on and which terminated fatally. A large stinking abscess had formed behind the cæcum and ascending colon, probably secondary to a suppurating appendicitis. A large opening was found in the cæcum communicating with the abscess. The man was suffering from marked septic absorption before the operation and he died 48 hours after it In other rare cases the pus has been discharged by ulceration into the bladder or rectum, but instances of this condition I have never seen. A certain proportion burst into the peritoneal cavity and produce a general suppurative peritonitis. It is now generally agreed that when the presence of pus is ascertained the case is one in which a better and more rapid result will be obtained by surgical interference than by natural means. The great difficulty is to be certain of the presence of pus. Perhaps, on the whole, the safest line of practice will be: When in doubt, operate. It is astonishing how rapidly pus may form. On Oct 13th, 1898, I operated on a girl, aged 12 years, about 60 hours after the appearance of the first symptoms, and I found a sloughing appendix, which had perforated, lying in an abscess cavity. There was also some purulent inflammation about the coils of intestine, in the cæcum, and in the omentum in the right iliac fossa—the case was one of localised suppurative peritonitis. The abscess cavity was cleaned, the appendix was removed, and the patient made a good recovery.

In connexion with the subject an interesting problem here presents itself. Is it possible for pus, when it has once formed, to remain inert, to become encapsuled, and ultimately to become absorbed? I think that it is possible, and I have seen cases which I venture to think will not bear any other interpretation. I have operated on three or four cases of relapsing appendicitis in which I have not at all expected to find any pus and have found small quantities encapsuled. I feel that these patients have been subjected to great risks by the delay, although all of them made good recoveries In the foregoing classes general peritonitis very rarely takes place during the first attack.

III.—GANGRENOUS APPENDICITIS.

The greater part of the appendix may become gangrenous or a localised patch may form in its walls. It is in these cases that one, as a rule, finds a hard concretion near the cæcal orifice of the appendix. Here venous stasis is produced with a rapid œdema, and very quickly the micro-organisms finish the work of destruction so commenced. In some cases a rapid line of demarcation is formed and the gangrenous portion of the appendix may be found free—necrotic amputation. It is these cases which are so rapidly and tragically fatal, the patient dying in a short time from general peritonitis In other cases the purulent collection is limited by adhesions, so that the whole peritoneum is not [illegible] y be [illegible] per- [illegible] ion, [illegible] on- [illegible] ave been fortunate enough to have two successful cases of this kind in both of which there was very extensive peritonitis—I will not say general—associated with a gangrenous appendix.

CASE 1.—A woman, aged 29 years, was operated upon on April 11th, 1897. There was very extensive peritonitis with gangrenous appendix The appendix was removed and the peritoneum was drained. I do not think that I ever saw a patient who was so ill recover. Her hands and face were cold and blue after the operation and the pulse was very rapid, small, and feeble.

CASE 2.—A man, aged 22 years, was seen by me with Dr. O. T. Empey of Cross Hills He was suffering from complete gangrene of the appendix, and he was operated upon seven days after the onset. The abdomen was opened in the middle line There was extensive peritonitis. The appendix was removed and the peritoneum was drained. The patient made a good recovery.

The following three cases were fatal:—

CASE 3—A man, aged 21 years, was operated upon on June 29th, 1898. Five days after the onset gangrenous appendix was found with extensive peritonitis. The appendix was removed and the abdomen was drained.

CASE 4—The patient was a man, aged 25 years. The symptoms commenced on March 1st, 1896, and the patient was medically attended on the 7th. The operation was delayed till the 9th. The abdomen was opened in the right iliac region and a large abscess with extensive peritonitis was found. The appendix was not sought for, as the patient's condition would not permit of a prolonged operation. He died on March 14th. The appendix was removed at the post-mortem examination

CASE 5.—The patient was an adult, aged 29 years. The operation was performed in August, 1896, five days from the time of the attack. The operation was delayed for 48 hours. There was extensive peritonitis. The gangrenous appendix was removed and the peritoneum was drained. The patient died three days later. The appendix was completely gangrenous.

The diagnosis of appendicitis is often a very easy matter, but it is sometimes very difficult. Sometimes it comes with a sudden onset and sometimes with vomiting. The symptoms are acute pain in the region of the cæcum, generally radiating to the umbilicus, a quick pulse with a rise of temperature, a flushed face, and in some cases obstinate constipation and no passage of flatus. On examining the abdomen the movements of the abdominal wall over the cæcal region are seen to be limited. There are some fulness and tenderness in this region. It may be interesting here to discuss how this fulness is produced. Fæcal accumulation in some cases and in others adhesions to, and inflammatory changes in, surrounding parts, the anterior abdominal wall, intestines, and omentum may account for it. The latter is a very common cause I here show you some specimens in which the appendix was embedded in a mass of omentum which was removed with the appendix. In two or three instances I have found abscesses in the omentum. Other causes of the swelling are collections of pus and masses of coagulated lymph. The tender spot, McBurney's point, is often present. This can only be taken in association with other signs and symptoms in helping to make a diagnosis. It may be absent in cases of appendicitis and present in diseases not connected with the appendix.

In all cases a rectal examination should be made Frequently a distinct fulness can be felt on the right side of the pelvic brim, and the rectal mucous membrane is sometimes hot and œdematous, making the examination difficult. In the simple cases, after 48 hours, the symptoms may begin to subside and the signs may clear up in about 10 or 14 days. In the suppurative cases the symptoms will increase in severity and the signs will become more marked during the extension of the inflammatory process. The pulse will become more rapid, the abdomen more distended, and intestinal movements may be visible. When these conditions are present surgical interference must be discussed. The disease may advance a stage further, fluctuation may be obtained, and the abscess may either burst into the general peritoneal cavity or become evacuated by other routes. In the acute perforating cases the course of the disease is more rapid. Often there is an attack of pain in the right iliac region which comes on 24 or 48 hours before the greater pain and collapse associated with perforation The patients are often strong, active people and they will fight against the disease, going to business or doing their work until the onset of the perforation On seeing the patient soon after this has happened the pain will be found to be great The hands are cold and generally moist and the face has an anxious expression; it is flushed and it soon becomes dusky. The duskiness is not easily to be seen by artificial light, and if the pain should have been relieved by morphia the flushed face may quite mislead the medical attendant, so that the gravity of the condition may be under estimated and it is sometimes difficult to convince the friends that the patient is really seriously ill. The pulse will be small and very rapid and the temperature may be sub-normal. On examination of the abdomen it may either be greatly distended or there may be retraction, with the abdominal muscles as hard as a board, and the limbs drawn up. There may be no tumour felt in the cæcal region and no one spot may be more tender than another. The urine is scanty and sometimes suppressed and it contains albumin and indican.

This is a picture of a commencing acute general peritonitis due to some peritoneal catastrophe, and it is sometimes very difficult to make a diagnosis as to its exact cause. The making of a correct diagnosis may be nothing more than a shrewd guess. Appendicitis which has gone on to perforation, however, is by far the most common cause. Other causes are perforated gastric ulcers or duodenal ulcers, one of the many causes producing acute intestinal obstruction, and some cases of ruptured tubal pregnancy; in the latter condition the dominant symptoms are, as a rule, those of internal hæmorrhage. Still, in some cases it may be quite impossible to decide. For these conditions only one form of treatment is of any avail—that is, operation; and lately for these extreme conditions recent results have been decidedly encouraging. If no operation is done death takes place in a few days. There is great and frequent sickness, the tongue is kept moist, and there is pain in the abdomen The face and extremities become cold and livid, the pulse becomes rapidly quicker and is pegging out. The patient often remains quite conscious to the last moment, so that the friends cannot believe that the end is so near. In a few cases acute delirium may set in and some patients die comatose.

Many mistakes may be made in the diagnosis of appendicitis—renal and biliary colic, psoas or iliac abscess, hip-joint disease, and, in women, diseases of the uterine appendages. I have twice opened the abdomen in the region of the appendix expecting to find the organ embedded in a mass of adhesions, and I have found instead tuberculous disease of the cæcum. In one case the appendix was found and removed; in the other it was embedded in a tuberculous mass and was not seen. Both cases developed troublesome fæcal fistulæ and subsequently died from general tuberculosis. In the relapsing cases a careful search must always be made to exclude tubercle before recommending an operation. I have twice operated expecting to find malignant disease and have been greatly surprised to find that I had a simple appendicitis with very firm adhesions to deal with. In the first case the end of the appendix was firmly embedded in the omentum and around the end of the organ was a small abscess in the omentum connected with a small perforation. It was a very hard mass and was moveable. The patient had noticed it for some months and had lost considerably in weight. In another case a hard growth infiltrated the abdominal wall in the region of the appendix, forming a prominence which could be easily seen and felt, and from this a good deal of induration extended into the false pelvis. On cutting down I found the mass to be composed of hard fibrous tissue, evidently due to the organisation of inflammatory products resulting from a relapsing appendicitis. The appendix was successfully dug out. I have a case to record which is the converse of the last two cases. The patient was a man, aged 34 years, who was diagnosed by the medical man in charge and by one of my medical colleagues to be suffering from relapsing appendicitis—a diagnosis in which I quite concurred. I opened the abdomen and found malignant disease of the cæcum and a peritoneum studded with secondary growths. The last mistake I have to record is one which I venture to think few will have a chance of repeating. It was an encapsuled decomposing ectopic gestation situated in the cæcal region. As it is so unusual I will read brief notes of the case.

CASE 6.—The patient was a woman, aged 26 years, who was admitted into the Leeds General Infirmary on Nov 13th, 1897. The history of the case was as follows. On May 6th, 1897, the patient complained of an attack of pain in the right iliac region which was accompanied with vomiting and complete constipation lasting for two or three days. The attack kept her in bed for a week. Her medical man told her that she was suffering from a "stoppage of the bowels and inflammation." Though she had some pain every day she got up until June 18th. On this date a similar attack commenced but of greater severity; the bowels were confined for a week and they were then opened by enemata. At this time a swelling appeared in the cæcal region. During July, August, and September she had two more attacks, in the intervals of which she was not free from pain and was quite unable to attend to her household duties Three weeks before admission into the infirmary she had another attack of pain in the body which was accompanied with vomiting and constipation. At the end of three days the bowels were opened and although she was in pain she again got up. I saw her on Oct. 28th, when she was suffering from acute intestinal obstruction, with vomiting, constipation, and abdominal distension, and there was well-marked visible peristalsis. On rectal examination there was found a swelling of about the size of a closed fist in the cæcal region and there was some fulness in the right side of the pelvis. I made the diagnosis of recurrent appendicitis and advised her to come into the infirmary. This she refused to do. Soon afterwards the bowels were opened, the vomiting ceased, and the pain disappeared. The swelling diminished in size. She had another similar attack and she was admitted to the infirmary on Nov. 13th, 1897, and was operated upon on Nov. 21st. Ether was administered. An incision about four inches long was made obliquely in the right iliac region, commencing one and a half inches internal to, and a little above, the anterior superior spine. At a later stage of the operation another incision was made from the middle of this downwards and at right angles. The structures were divided down to the peritoneum, all bleeding points were stopped, and the peritoneum was opened. In the iliac fossa an oval swelling presented. Its lower limits were close to Poupart's ligament. It extended inwards to the pelvic brim and was covered with firm fibrous tissue. There were many adhesions to the surrounding viscera. The parts around were carefully packed and an opening was made with the finger about the middle of it, near Poupart's ligament. The swelling was found to contain some foul and stinking pus and a mass of decomposing fœtal bones of about the fourth month. These were removed and the cavity was cleansed and packed with gauze for drainage. The edges of the opening were then stitched to the peritoneum and the peritoneum was closed. The muscles and skin were sutured separately. The patient made a good recovery and left the infirmary on Feb. 5th, 1898, the wound having quite healed.

TREATMENT.

I shall not discuss the general treatment of this condition, but I would urge, if there is no improvement in the patient's condition after 48 hours from the onset of the attack, that those who will be responsible for the operation should have a chance of seeing the case and of deciding at this stage whether or not an operation should be performed. I have never yet regretted operating, but I have often regretted that operation has not been decided upon earlier. There are no golden rules as to when to operate or when not to operate. Each case must be carefully studied. It is an advantage to operate when there is no pus, for then the appendix can be removed by a muscle splitting operation which is much less likely to produce a hernia. When pus is present and is localised one must work very carefully so as not to infect the peritoneum. This can be done by carefully using strips of gauze and wiping out as one goes along; in the majority of these cases it is necessary to drain. The pus is generally found about the appendix extending to the pelvic brim and perhaps into the pelvis, behind and to the outer side of the cæcum, and the parts in front of the cæcum. Here it is shut off from the general peritoneal cavity often by recent adhesions to the omentum which may be infiltrated with pus. I think that the more experience one has the more one is inclined to search for and remove the appendix; but there are certain cases in which the condition of the patient will not admit of this, where we must simply be content to open the abscess and drain, leaving the appendix Fortunately a fair percentage of these cases may recover and some of them may never have a relapse.

The abdominal wall in the region of an inflamed appendix is generally very vascular. Often the muscles and intermuscular planes are œdematous and sometimes purulent. In the gangrenous cases with extensive peritonitis something heroic must be done for so desperate a condition: more extensive exposure of the peritoneum for cleansing and drainage getting the bowel to act by saline purgatives, &c.

Formerly all cases of appendicitis were considered to belong to the province of the physician, but now surgery has put forward such strong claims that in a certain number of cases an operation must be performed, and in others the advisability of an operation must be discussed. I have endeavoured to illustrate this paper with as many personal observations and experiences as possible. I hope it may not

[Mr. Littlewood illustrated his address with about 30 specimens which he had recently removed. The specimens [illegible] so that they could be easily [illegible] and the different patho-

ON THE RÔLE PLAYED BY THE SPLEEN IN THE PANCREATIC DIGESTION OF PROTEIDS.

BY HENRY F. BELLAMY.

It is probable that no organ of the body has furnished such abundant food for physiological reflection and research as the spleen. In all ages speculation has been rife as to the rôle played by it in the animal economy, and observers in all countries have not been wanting who have ascribed more or less hypothetical functions to an organ which, as they justly argued, possessing such overwhelming importance as regards position and blood supply, should in the natural order of things be possessed of functions equally weighty. Attempts, however, at the solution of the problem have enjoyed only a limited measure of success, chiefly in face of the almost insurmountable difficulty that in all animals, from man downwards, possessing a spleen the organ can be surgically extirpated without *apparent* disadvantage to the organism as a whole. It is the purpose of the present article, without any reference to the possible and perhaps equally important manner in which the spleen acts in other departments of the animal economy, to consider it in the light of a powerful, and indeed essential, factor in the pancreatic digestion of proteids and to bring forward, as briefly as possible, such evidence as may be forthcoming in support of such a view.

While pursuing my own work here in Lausanne it has been my privilege and pleasure to have had many conversations on this subject with Professor A. Herzen, the distinguished occupant for many years past of the chair of Physiology at the Lausanne University, a physiologist who, formerly in conjunction with Professor Schiff (the original proclaimer of the doctrine of the functional co relation of spleen and pancreas) has devoted practically his whole lifetime to this and kindred questions, and it is in deference to his wish to invite the attention and criticism of English physiologists to what appears to him and his supporters an important contribution to our present meagre knowledge of the spleen, that the present article is penned

Before proceeding to a detailed discussion of the evidence appertaining more nearly to the question, it would be as well to recall as briefly as possible several fundamental facts in connexion with the peptonisation of proteids by the pancreatic juice, for the discovery of which physiology is largely indebted to the researches of Corvisart, Schiff, and Meissner. The experiments of these observers were performed both with the natural juice and with infusions of the gland For the study of the natural juice experiments on living animals (principally on dogs and cats) were conducted [illegible] ways 1 By establishing *pancreatic* [illegible] secretion of the gland was drawn [illegible] cannula fixed in the duct; this method, although possessing the disadvantage that the fluid flowing through the cannula soon ceased to be normal, gave in successful cases results identical with the two following 2 By causing *duodenal fistulæ* analogous to gastric fistulæ and observing the progress of digestion in the living and normal duodenum of small cubes of coagulated albumin enclosed in coverings of fibrous membrane, the latter having the property of resisting the action of the pancreatic juice without preventing its penetration; by this means it could always be rendered certain that the albumin was digested by the pancreatic and not by the gastric juice, since the latter would first destroy the envelope. The presence of the cannula interfered in no way with the health of the animal 3 By isolating the whole duodenum after introducing into it a measured quantity of boiled albumin between two ligatures placed respectively at the pyloric and jejunal ends, the pancreatic the experiment, the bile could be excluded. In order, however, to observe the progress of peptonisation by this method, it was necessary, after some hours, to sacrifice the animal.

The results claimed from these experiments in so far as they concern the present question were briefly these. Corvisart found that in dogs in full digestion there was for a certain time a constant rise to maximum in the digestive power of the pancreatic juice, succeeded by an equally constant fall to minimum. The maximum was attained during the eighth hour after the ingestion of a meal, the minimum from the thirteenth to the eighteenth hours. Meissner announced that in fasting animals the pancreatic juice possessed little or no peptonising power. Schiff,[1] after a number of experiments on such animals as rats, guinea-pigs, rabbits, and young dogs or dogs of small breed, found that during fast the pancreas really possessed almost no peptonising power; the albumin imprisoned in the duodenum remained there for whole hours without dissolving, the infusion of the gland giving results equally negative. On the other hand, in the case of ravens and adult dogs of large breed the pancreas preserved during fast a certain digestive power, even in animals in a condition of complete fast which had digested a copious meal the day before; under these circumstances, indeed, the infusion of the whole pancreas of a large dog was capable of digesting from 50 to 60 grammes of albumin. In such dogs this condition of weak digestion was maintained until towards the fourth hour after the meal, after which time digestion proceeded very much more rapidly, so that at the time of maximum the pancreatic infusion was capable of digesting from 50 to 60 grammes of albumin. As regard cats and small dogs, he was able to confirm the results of Corvisart. By these experiments, then, the above-mentioned observers succeeded in establishing the following two facts: (1) that the activity of the pancreatic juice or of an infusion of the gland is not continuous but intermittent, and (2) that maximal activity appears regularly during the culmen of gastric digestion (from six to eight hours after a meal) at which time it is very considerable

Passing now for the moment from the pancreas to the spleen we will proceed briefly to examine the behaviour of this organ in relation to digestive phases. Lauret and Lassaigne in 1825 discovered that the spleen began to become congested at the moment when the stomach discharged chyle abundantly into the duodenum; that this is, however, merely a coincidence is shown by the fact that the congestion also occurs after ligature of the pylorus Dobson in 1847 discovered that in a dog three hours after a meal the spleen is still as small and as anæmic as during fast; that it commences to dilate in the fourth hour after a meal; at five hours after it has attained its maximal turgescence, decreasing afterwards from the seventh hour to attain towards the twelfth its minimal volume Landois in the same year found that in the rabbit the relative weight of the spleen to the body-weight of the animal was the same two hours after a meal as after 48 hours of fast; that it increased considerably from the fifth hour, remaining high until the twelfth hour In 1835 Schönfeld, under the direction of Van Deen, compared the weight of the spleen with that of the body of six rabbits of the same age fasting and digesting His results are given in the following table:—

Relation between Weights of Spleen and Body during Fasting and Digestion.

Hours after meal	Weight of spleen	Proportion to body-weight
0	3	1 : 2180
2	4	1 : 1137
5	6½	1 0738
8	5	1 : 0996
12	5	1 : 1062
24	2½	1 2140

Observations on the human body have confirmed these facts Dittmar and Vogel in 1850, studying from this point of view the changes in volume of the spleen of man by means of percussion, found that it began to swell four hours after a meal, reached two hours later its maximal volume, and gradually diminished afterwards to its minimum.

---

[1] Recueil des Memoires Physiologiques, vol. iv., cap Pancreas et Rats. Lausanne, 1898

The striking synchronism in the splenic congestion and the presence of trypsin in large quantity in the pancreatic juice or in an infusion of the gland was observed by Schiff and caused him to repeat all his former experiments on the tryptic digestion of albumins, this time on animals in which the spleen had been for some time removed and on others in which it was prevented from dilating by ligature of its hilum at the time of the experiment. He experimented in this way upon a very large number of dogs and cats; nearly all his experiments were double—i.e., performed at the same time and in the same manner on two animals selected so as to resemble one another as much as possible, and in only one of which had the spleen been extirpated or ligatured. These experiments were of two kinds: (1) those conducted with pancreatic infusions, and (2) those carried out in the living duodenum, the following being typical examples.

I. *Infusions.—Ligature of the hilum of the spleen.*—Two cats, after fasting for 19 hours, received as much meat as they would eat; one hour afterwards they were etherised and the spleens, which were found to be in a state of contraction, were brought out through a wound in the abdomen and their hila were encircled by strong thread; in one of the animals the hilum was firmly tied, but in the other it was simply encircled and a knot was tied, leaving the splenic circulation perfectly free (this was done in the endeavour to equalise traumatic conditions as much as possible). The spleens were then replaced in the abdominal cavity and the wound was sutured. On recovering from the anæsthesia the animals did not appear to suffer. They were killed six hours later. Gastric digestion was found to be more advanced in the animal in which the splenic vessels were tied; the pancreas of both was cut up into small fragments and infused with 100 cubic centimetres of water for an hour at 35° C; the liquid was afterwards decanted and returned to the warm chamber together with cubes of albumin. Result.—In seven hours the pancreatic infusion of the cat in which the hilum was not ligatured digested 17 grammes of albumin; that of the other did not digest at all even at the end of 12 hours.

This experiment was performed on a large number of cats and dogs and always gave the same result. In spite, however, of the perfection of gastric digestion in the operated animals, it was possible to lay at the door of traumatism the absence of duodenal digestion; to correct this the experiment was repeated as follows.

Extirpation of the spleen.—Two dogs, one normal, the other having undergone splenectomy a month previously but at the time of the experiment in perfect health, were operated upon, while fasting, as follows: etherisation, ligature of the pylorus, injection into the stomach per œsophagus laid bare and opened of 50 grammes of peptone and two grammes of dextrin; to allow drainage of swallowed saliva the œsophagus was ligatured below the opening. Both animals were killed five hours later and each pancreas was infused for three-quarters of an hour in 100 cubic centimetres of water at 35°C. Although death had occurred before the most favourable moment for the experiment—i.e., in advance of the summit of the splenic curve—the infusion coming from the dog with the spleen intact digested 17 grammes of albumin in 17 hours, while the other digested nothing even in 18 hours. Numerous experiments made in this manner always gave the same result. The spleenless dogs had in many cases undergone splenectomy several months before the experiment, and the determination in them of perfect conditions of health was always a matter of great care.

II. *Experiments in the living duodenum.—Ligature of the duodenum at both ends.*—Two dogs after fasting for 17 hours received as much meat as they would eat and immediately afterwards were operated upon as follows: etherisation, laparotomy, ligature of the pylorus and of the bile duct, introduction into the duodenum of from 30 to 40 grammes of albumin, and ligature of the jejunal end. In one of the animals the splenic hilum was also ligatured. Both were killed seven hours later. Result.—In the dog with the splenic hilum tied the albumin was found to be intact; it had, however, disappeared in the other.

This experiment was also several times repeated on animals which had undergone splenectomy a long time previously and always yielded the same result; it is, of course, capable of being combined with the preceding by making an infusion of the pancreas after the death of the animals. Such infusions give results in harmony with those furnished by the duodenum itself. Further, it will be remembered that in the pancreatic juice of dogs of large breed Schiff generally found, even while fasting, a certain quantity of trypsin; when the same were spleenless, however, he was unable to find any.

Digestion in the normal duodenum provided with a fistula.—A duodenal fistula was established in a dog. After complete recovery a measured and constant quantity of albumin was introduced every day into the duodenum enclosed in a small envelope of fibrous membrane fixed to the cannula by a thread some centimetres long. The progress of digestion was then observed, the following results being obtained. 1. When the animal was fasting the albumin took from five to six hours to become dissolved. 2. When the albumin was introduced into the duodenum during the two to three hours immediately following the ingestion of a meal by the animal it remained unchanged. 3. When introduced four hours after a meal it disappeared very quickly, in about half the time, in fact, occupied during fast. These facts having been duly noted the spleen was then extirpated and after complete recovery the same experiment was repeated; very different results were now obtained. Whether fasting or in full digestion the time taken for the digestion of the albumin was exactly the same —viz., from five to six hours. The acceleration in the peptonisation which had formerly appeared after the fourth hour of digestion and which coincided both with the appearance of trypsin in the pancreatic juice and with the dilatation of the spleen, was now absent. The slow digestion (from five to six hours) in this experiment was probably entirely due to the secretion of the duodenal glands which possess only a very feeble digestive power; the active, rapid digestion was due to the appearance in large quantity of trypsin in the pancreatic juice, a phenomenon wanting in the spleenless animal.

The researches of Schiff, of which the above are only a few typical examples, thus lead him forcibly to the belief that after extirpation of the spleen, or when the organ is prevented from dilating by ligature of its hilum, trypsin fails to appear in any considerable quantity in the pancreatic juice or in an infusion of the gland during that stage of digestion in which in the intact animal it is normally present. In other words, he was warranted in concluding that not only the presence of the spleen but also its congestion is necessary to the abundant formation of trypsin. The pancreas of an animal deprived of its spleen behaves always (even in full digestion) in the same manner as that of a normal animal in a state of fast. Several years later M. Herzen being then Schiff's assistant in his laboratory at Florence, the latter resolved again to repeat all his experiments on the influence of the spleen upon the production of trypsin. M. Herzen thus assisted in this repetition, glycerine (after the proposal of von Wittisch) being this time employed as the vehicle of the digestive infusions. In the years which followed M. Herzen himself many times repeated the experiments, sometimes making use of glycerine, sometimes of boric acid, his own vehicle. With certain rare exceptions, easily capable of explanation, they always yielded the same result.

Such were the facts and they formed evidence striking enough. The differences observed were so enormous as to exclude all possibility of doubt. Schiff endeavoured to interpret the facts by the following theory. During the congestion of the spleen a substance is produced within it which, carried away by the blood, gives to the pancreas the wherewithal to form its peptonising ferment.

The whole question was received by physiologists with complete scepticism. The experiments of Schiff, instead of being repeated, were opposed by arguments and objections purely theoretical, and finally, not only was his theory rejected, but also the facts which he had observed. Some attempts were indeed made to reproduce the fundamental fact, but they were carried out with a superficiality and ignorance of the necessary experimental conditions which reduced the value of their results to practically nothing.

In 1872, however, the theory of Schiff received a rude shock through the great discovery of the zymogens by Heidenhain and his pupils. From the researches of this observer it appeared that as the gastric mucous membrane forms at the outset hardly any active pepsin, but a zymogen accumulating in its glands in the intervals of digestion, so the pancreas does not at once elaborate active trypsin but a

ditions and in a certain phas
substance being, of course,
trypsinogen or protrypsin. The researches of Heidenhain are well known and it suffices to recall here only one or more essential points; thus from them we know that the pancreas of a fasting dog contains little or no trypsin, but merely trypsinogen, consequently its glycerine infusion possesses little or no digestive power; the infusion, however, of a dog in full digestion digests rapidly and copiously because it contains trypsin. If the pancreas of a fasting dog be divided into two equal portions, one of which is infused at once and the other only after an exposure of 24 hours to the air, the first is found to be inactive while the other is immediately and energetically active, from which it is clear that the inert pepsinogen which it contains becomes spontaneously transformed into active trypsin; indeed, it suffices to pass a current of oxygen through a pancreatic infusion, rich in pepsinogen and poor in trypsin (an inactive infusion) to transform it into an infusic
proportional to the amount of
This transformation, then,
oxidised trypsinogen.

The fact observed by Heidenhain of the continuous formation and storing up of trypsinogen in the pancreas and its subsequent transformation into trypsin during the culmen of gastric digestion proved that the former substance at any rate enjoyed an origin quite independent of all influence outside the pancreas itself, and the hypothesis of Schiff as to the intervention of the spleen seemed in consequence to be at fault. But it was only the theory of Schiff which suffered by these new revelations; as far as the experimental results of the two observers were concerned physiologists were face to face with two series of apparently contradictory acts—apparently because facts properly observed can never stand in contradiction with one another and when they appear to do so it is merely because the interpretation of them is either false or incomplete. It fell to the lot of M Herzen to unravel the tangled hypotheses It appeared to him that by modifying the hypothesis of Schiff as to the manner in which the spleen acts as a tryptogene, a fusion of the respective facts of Schiff and Heidenhain could be brought about, and that far from being antagonistic they could be shown to be reciprocally corroborative. He argued thus: since the zymogen, even in splenectomised animals, is being continuously elaborated, and therefore independently of the spleen and its periodical congestion, and that it accumulates in the gland cells during fast, but that it becomes rapidly and copiously transformed into trypsin only in the presence of the spleen and in direct proportion to its dilatation, it would seem feasible that the spleen produces by "internal secretion"
own substance, which, carried
transforms the inert zymogen
creas, into active trypsin destined to pass into the secretion of the gland, and that the influence exercised upon the zymogen by this product of the spleen seemed to be a condition *sine quâ non* for the transformation of the former into trypsin, at least in the living pancreas, since in the dead organ or its infusion it is so transformed by direct oxidation This hypothesis of Herzen would seem to be further confirmed by the fact gleaned from the researches of both Schiff and Heidenhain—to wit, that the holding in zymogen of the pancreas at a given moment either of fast or digestion is always in inverse ratio to its holding in trypsin and *vice versâ*, while the latter is always in direct proportion to the spleen dilatation

So far so good. But Herzen reasoned further. If the spleen really produces during its congestion a substance which brings about the transformation of the pancreatic zymogen into trypsin it would then be possible to seize upon this substance in the spleen itself while in its turgescent condition (from six to seven hours after a meal) and by at once making an infusion of it and mixing a certain quantity of this splenic infusion with pancreatic infusion made from the pancreas of a fasting animal (very rich in zymogen and very poor in trypsin and consequently nearly inactive) there could be obtained *in vitro*
ypsin
easily recognisable
in a
given time. The c
very
simple, consisting merely in mixing with the same pancreatic infusion that of a contracted and anæmic spleen; in order to observe whether it would have the same effect as that of the spleen dilated and engorged with blood. Artificial digestions actually carried out with these infusions gave which had been added infusion of engorged spleen digested rapidly and copiously, indeed it had often completely digested its dose of proteid by the time that the other two, if digesting at all, had barely commenced. The mixed infusions thus behaved in the same way as a pancreatic infusion taken at the culmen of digestion.

A large number of similar experiments were made with aqueous, boric, and glycerine infusions, each being double—i.e., performed in two separate series of vessels, the one containing finely divided fibrin and the other equal-sized cubes of coagulated albumin. The results were always the same Technical points gleaned from these experiments appear to have been that the watery splenic infusions work more energetically than others but have the disadvantage of not being able to be preserved for more than one or two days. Glycerine infusions can be preserved indefinitely, but even when diluted with water they retard the digestion to such an extent as to allow the spontaneous transformation of the zymogen into trypsin; boric infusions keep well and do not retard digestion, but even they also permit the slow spontaneous oxidation of the trypsinogen; this disadvantage is, however, compensated for by the rapidity with which they digest. Fibrin digests very much quicker than albumin and consequently its use better demonstrates the difference in the activity of liquids poor and rich in trypsin. In order to obtain very considerable differences rapidly—in from two to three hours—it is preferable to make use of fibrin, the boric infusion of pancreas, and the aqueous infusion of spleen Further, in order that the various liquids for comparison shall contain the same amount of zymogen, Herzen adds to the pancreatic infusions which are to digest alone—i.e, without admixture of splenic infusion—the same volume of the vehicle with which was prepared the splenic infusions, added to the other portions. Finally to render all his experiments uniform and directly comparable Herzen always works with constant quantities of infusion and of albumin or fibrin (usually 10 cubic centimetres of infusion and 10 cubic centimetres of proteid) Below is given a typical example of such an experiment with results obtained in three instances.

In a temperature of 40° C. are placed two sets of four vessels, a set for fibrin and albumin respectively; in them are placed the following liquids:—No. 1 Pancreatic infusion of a fasting animal diluted with twice its volume of sterilised distilled water. No. 2 The same diluted by the same volume of saturated solution of boric acid No. 3. The same diluted by the same volume of boric infusion of spleen No. 4 The same diluted by the same volume of aqueous infusion of spleen.

rapidly in contact with trypsin. It would be difficult to obtain in a series of experiments a harmony more complete or a sequence more natural upon the researches of Schiff and Heidenhain. Herzen therefore believes himself justified in concluding that in the living pancreas the trypsinogen becomes transformed into active trypsin under the influence of a substance produced in the spleen, in a quantity proportional to the degree of its congestion.

uring its dilatation is engorged with blood. The splenic infusions exhibited were intensely coloured by dissolved hæmoglobin—*ergo*, the undoubted and considerable acceleration in digestion obtained by adding such a liquid to another containing trypsinogen could be quite simply explained by the rapid oxidation of the zymogen at the expense of the hæmoglobin. This objection disconcerted Herzen in no inconsiderable degree and he lost no time in making it the subject of experimental inquiry. He at length succeeded in disproving it by the following excellent experiment. The pancreas of a normal fasting dog was infused in pure glycerine and the infusion was divided into eight equal portions These eight portions were mixed with eight samples of blood received directly into a double volume of glycerine, of which four came from a fasting dog and four from a dog in full digestion with the spleen greatly dilated. The four samples were taken in both animals from (1) the femoral artery, (2) the femoral vein, (3) the splenic artery, and (4) a large splenic vein. The eight portions were then given the usual dose of fibrin and placed at a temperature of 40° C. Now, it is evident that the femoral and splenic arterial blood of the two animals contained more oxygen than their venous blood; the former, then, according to Heidenhain, should exercise a powerful influence on the digestion, equal in the two dogs. On the other hand, according to Herzen, the splenic venous blood alone should exercise this influence and especially that of the digesting animal. The result of the experiment was as follows. After one hour there was still no trace of digestion under the influence of the femoral blood, arterial or venous, nor of the splenic arterial blood of the fasting dog; first traces of digestion were beginning to manifest themselves under the influence of the splenic venous blood of this animal. Digestion was rather advanced in the case of the femoral arterial and venous blood and splenic arterial blood [illegible] fibrin had almost entirely dis- [illegible] of the splenic venous blood of [illegible]

The answer could not be *clearer: the product of the* internal secretion of the spleen, borne therefrom by the circulating blood, is present during the period of the dilatation of the spleen in feeble but appreciable quantity in the blood of the general circulation and abundantly in the splenic venous blood. The venous blood returning from the contracted spleen only contains it in very small quantities. This experiment, several times repeated, always gave the same result, showing that it is not the blood as such which favours the transformation of pancreatic zymogen into trypsin, but that, by picking up from the spleen the unknown substance possessing this property, the blood becomes its vehicle and means of communication with the pancreas.

At the International Congress of Physiologists, held at Berne in 1895, Herzen exhibited a second series of specimens preserved as an objective document of results arrived at by another method in which use was made of concentrated glycerine infusions Under these conditions digestion is extremely slow even in the case of fibrin; even should the liquid already contain trypsin but little diminution of the fibrin can be observed after the lapse of several days, and at the same time an effective check is put upon the spontaneous transformation of the zymogen into trypsin. In the infusion of the pancreas alone the fibrin maintains indefinitely its original bulk; in the mixture of the two infusions it gradually dissolves and finishes at the end of three or four weeks by disappearing altogether. The specimens shown by Herzen at this Congress were already one year old. I have seen others in his laboratory at Lausanne which have been preserved for six years, forming, together with those originally exhibited at Strasburg, a striking object-lesson for those following his teaching.

From the bulk of evidence collected by Herzen there thus seems to be very little room for doubt that apart from hæmatopoietic, and possibly allied, functions possessed by the spleen, the organ furnished a product, of "internal secretion" which causes in the pancreas the transformation of its inert zymogen into active trypsin.

I shall, in conclusion, briefly examine the criticisms to which the researches of Schiff and Herzen have been exposed. It is not proposed to consider *objections* purely speculative and theoretical, since, however plausible the arguments of such may appear, they cannot be brought into the same category with established facts; I shall therefore concern myself only with those having at least the semblance of being supported upon an experimental basis; and even in these cases it will be apparent with what lightness of heart the critics of Schiff and Herzen have undertaken their task—a lightness of heart only equalled by that of a large number of physiologists who have given these criticisms their support. Now the first rule required to be observed in endeavouring to test the results of a particular line of research consists in the exact reproduction of the original fact which it is sought to establish, a proceeding only rendered *possible by the second observer* reproducing accurately the experimental conditions under which the first laboured. Having done this the way is then open for him to repeat the several experiments, modifying them in what way he will in order to detect in them possible sources of error. This elementary rule appears to have been entirely overlooked by the opponents of Schiff and Herzen, as will readily be gathered from the following examples of their *modus operandi*.

In 1868 the Italian physiologist Lussana extirpated the spleen in three dogs and killed them later in order to ascertain whether the extract of their pancreas would digest coagulated albumin. One of his dogs suffered from a chronic peritonitis, another from an inflammatory condition of the pancreas. The pancreatic infusion from these two animals digested minimal quantities of albumin (maximum 0·25 gramme) in 24 hours. The third dog appears to have been healthy and its pancreas digested 1·10 grammes. The animal had, however, been killed three hours after a meal—i.e., at a moment when, even had it been in possession of its spleen, that organ would not yet have commenced to become congested. The experiment, therefore, gave the result which might be expected—viz., no digestion, for nobody would accept seriously the digestion of 1·10 grammes, knowing that the pancreas of a dog when digesting can dissolve from 50 to 60 grammes of albumin, for which, however, it is not only necessary that the spleen should be intact but also that it should be maximally congested, a phenomenon only commencing from *six to seven hours after a meal. Nevertheless*, Lussana concluded that in the absence of the spleen the pancreas digests just as well as when it is present, and that the diseased pancreas losing its peptonising property it was natural that Schiff had not found this property "*chez ses lapins dératés.*" It would seem evident that not only had Lussana never seen a true digestion by an active pancreas, but also that he had never read the work which he professed to criticise. This, however, did not prevent *the majority of physiologists from blindly accepting* his conclusions and declaring that the hypothesis of Schiff had been unable to withstand experimental proof, and in spite of the fact that Herzen, then Schiff's assistant, had immediately issued a severe analysis of Lussana's publication, to which, however, the latter never replied. For 10 years after Lussana's statement continued to be made, the name of Herzen being now coupled with that of Schiff, without the least attempt at experimental inquiry, Herzen published later an account of his own researches, the equally surprising results of which, obtained by an altogether new method, entirely confirmed those of Schiff.

In 1893 two French observers, Carvallo and Pachon, communicated to the *Société de Biologie*, and also published in the *Archives de Physiologie*, an account of some experiments said to be performed according to Herzen's method and of which the results were entirely negative. One would again be inclined to ask whether the authors had read the work which they undertook to criticise, for they, like Lussana, altogether neglected the conditions most essential to the experiment. Owing to too prolonged extraction they allowed a large part of the zymogen to become transformed into trypsin *before even commencing their digestive experiments*, and in the course of digestions equally prolonged the transformation of the remaining zymogen was also allowed to take place, so that in summing up their results they were unable to perceive any difference in the activity of their infusions. Herzen replied by drawing the attention of the authors to this double source of error which deprived their experiments of all value. Pachon, now professor of physiology at Bordeaux, fully comprehended the gravity of these errors and resolved to do now what might reasonably have been expected of him and his colleague in the first instance—conscientiously to repeat the experiments of Schiff and Herzen by conforming to their directions; the result was that Pachon confirmed all their results and, together with his *new collaborator Gachet, was entirely* won over to their point of view. Nay, they did more, they invented an entirely new experiment, at once original and ingenious, which consisted in realising *in vivo* what Herzen had hitherto only done *in vitro*. This experiment was as follows.

A dog, which a long time previously had undergone splenectomy, was anæsthetised and half its pancreas was removed and immediately infused; at the same time a normal dog, in the height of digestion, was killed and its congested spleen was infused in water and this infusion was injected into the venous system of the spleenless dog; from 15 to 20 minutes afterwards the remaining half of the pancreas of the latter dog was infused exactly like the first; of the two *infusions when* given fibrin or albumin, the second only digested rapidly and copiously.

It would be thought that after proof so absolute the doctrine thus established by six different methods, first by Schiff and Herzen and afterwards by Pachon and Gachet, would enjoy immunity from *attacks so reckless as the* preceding. Such, however, was not to be the case, for last year a Russian observer, Popelski, conducted a series of experiments in which he succeeded in combining the error of Lussana with those initially made by Pachon in conjunction with Carvallo. In both normal and splenectomised cats he collected the pancreatic juice by means of a cannula introduced into the duct of the gland, and was

The following charts graphically illustrate the quality of the results obtained in the case of fibrin. The albumin digestions are omitted, since, being necessarily so slow, they show but imperfectly the influence of the splenic infusions in bringing about rapid and copious digestion quite independently of spontaneous transformation of the zymogen. For the same reason the time of observation is restricted to six hours. The numbering of the curves in these charts corresponds to that of the liquids in the account of the experiment.

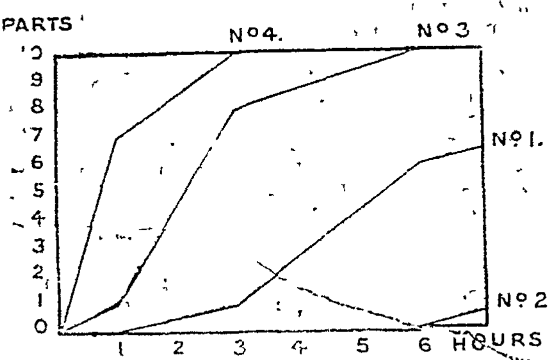
For the same reason the time of observation is restricted to six hours. The numbering of the curves in these charts corresponds to that of the liquids in the account of the experiment.

CHART 1.

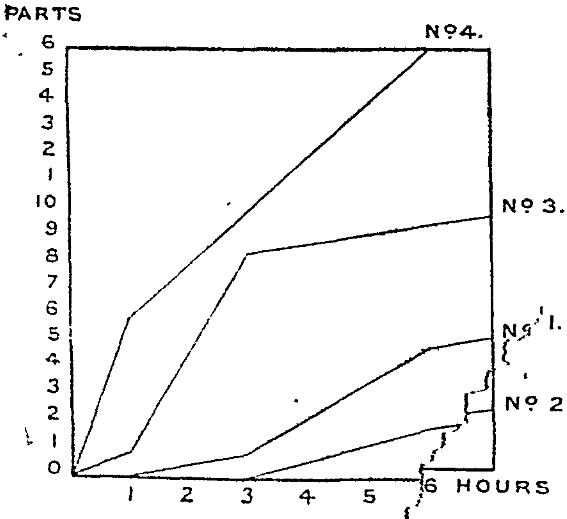


An ordinary digestion in which the fibrin to be digested is considered to be divided into 10 equal parts, the curves showing the number of such parts digested in the time-limits figured on the base line. Notice the immediate and copious digestion under the influence of the splenic infusions and that No. 2 is barely commencing to digest even after six hours.

In these experiments the enormous acceleration in the digestion of the fibrin under the influence of the two splenic infusions is very evident. As for the albumin it only digests in an appreciable manner when under this influence; the activity of No. 4 may give rise to the suspicion that it was due to the neutralisation of the boric pancreatic infusion by the aqueous splenic infusion. To this objection, however, No. 3 conveys a sufficient reply.

In many of Herzen's experiments the digestion performed by the mixture of the two infusions has been still

CHART 2.

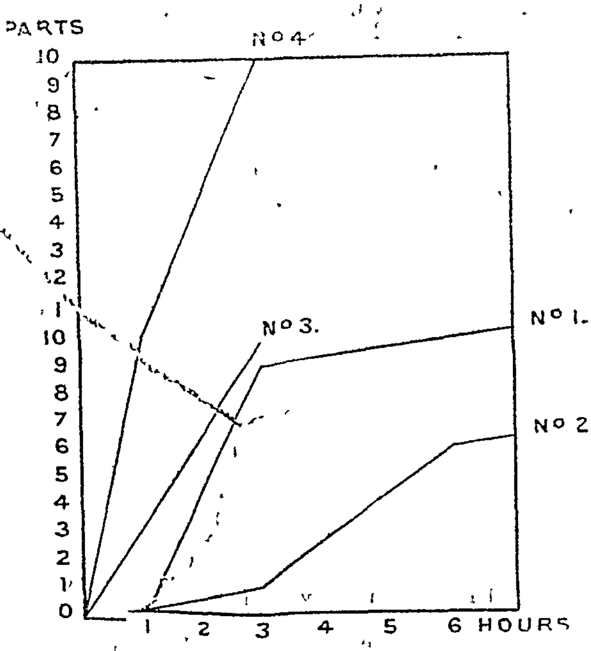


A digestion in which to the initial dose of [illegible] parts of fibrin a further 10 parts have been added, of which more than half have been digested by No. 4 at the end of six hours.

very much more rapid. He has, in fact, sometimes seen the initial dose of fibrin totally disappear at the end of the first hour. In these cases a second dose of fibrin added by him disappeared in its turn before the third hour. This activity in the digestion of the fibrin was also accompanied by a corresponding acceleration in that of the albumin. The latter, however, was rarely entirely dissolved even after 24 hours. This substance has therefore never given the enormous differences yielded by the fibrin which liquefies extremely rapidly in contact with trypsin. [illegible] obtain in a series of experiments : [illegible] or a sequence more natural upon the researches of Schiff and Heidenhain. Herzen therefore believes himself justified in concluding that in the living pancreas the trypsinogen becomes transformed into active trypsin under the influence of a substance produced in the spleen, in a quantity proportional to the degree of its congestion.

At the German Congress of Medicine held at Strasburg in 1886 Herzen exhibited several graduated flasks containing the residua of fi[illegible] number of his [illegible] est [illegible] decanted and [illegible] examined them [illegible] th [illegible] the residua left [illegible] those of the mixtures of the [illegible] splenic infusions were very obvious. In a private conversation with Herzen, however, Heidenhain made the following criticism. It is well known that the pancreatic zymogen is very greedy of oxygen; on the other hand, the spleen during its dilatation is engorged with blood. The splenic infusions exhibited were intensely coloured by dissolved hæmoglobin—*ergo*, the undoubted and considerable acceleration in digestion obtained by adding such a liquid to another containing trypsinogen could be quite simply explained by the rapid oxidation of the zymogen at the expense of the hæmoglobin. This objection disconcerted Herzen in no inconsiderable degree and he lost no time in making it the subject of experimental inquiry. He at length succeeded in disproving it by the following excellent experiment. The pancreas of a normal fasting dog was infused in pure glycerine and the infusion was divided into eight equal portions. These eight portions were mixed with eight samples of blood received directly into a double volume of glycerine, of which four came from a fasting dog and four from a dog in full digestion with the spleen greatly dilated. The four samples were taken in both animals from (1) the femoral artery, (2) the femoral vein, (3) the splenic artery, and (4) a large splenic vein. The eight portions were then given the usual dose of fibrin and placed at a temperature of 40° C. Now, it is evident that the femoral and splenic arterial blood of the two animals contained more oxygen than their venous blood; the former, then, according to Heidenhain, should exercise a powerful influence on the digestion, equal in the two dogs. On the other hand, according to Herzen, the splenic venous blood alone should exercise this influence and especially that of

CHART 3.



An exceedingly active digestion in which the whole of the second dose of 10 parts of fibrin has been digested by No. 4 in three hours. Corresponding activity in unmixed infusions. No second dose was added to No. 3, the initial dose of which had been entirely dissolved at the end of three hours.

the digesting animal. The result of the experiment was as follows. After one hour th [illegible] s still no trace of digestion [illegible] blood, arterial or venous, [illegible] of the fasting dog; first [illegible] og to manifest themselves under the influence of the splenic venous blood of this animal. Digestion was rather advanced in the case of the femoral arterial and venous blood and splenic arterial blood of the digesting dog; the fibrin had almost entirely disappeared under the influence of the splenic venous blood of the same animal.

The answer could not be clearer: the product of the internal secretion of the spleen, borne therefrom by the [illegible] blood. The venous blood returning from the contracted spleen only contains it in very small quantities. This experiment, several times repeated, always gave the same result, showing that it is not the blood as such which favours the transformation of pancreatic zymogen into trypsin, but that, by picking up from the spleen the unknown substance possessing this property, the blood becomes its vehicle and means of communication with the pancreas.

At the International Congress of Physiologists, held at Berne in 1895, Herzen exhibited a second series of specimens preserved as an objective document of results arrived at by another method in which use was made of [illegible] usions Under these conditions [illegible] even in the case of fibrin; even [illegible] contain trypsin but little diminution of the fibrin can be observed after the lapse of several days, and at the same time an effective check is put upon the spontaneous transformation of the zymogen into trypsin. In the infusion of the pancreas alone the fibrin maintains indefinitely its original bulk; in the mixture of the two infusions it gradually dissolves and finishes at the end of three or four weeks by disappearing altogether. The specimens shown by Herzen at this Congress were already one year old. I have seen others in his laboratory at Lausanne which have been preserved for six years, forming, together with those originally exhibited at Strasburg, a striking object-lesson for those following his teaching.

From the bulk of evidence collected by Herzen there thus seems to be very little room for doubt that apart from *hæmatopoietic, and possibly allied, functions possessed* by the spleen, the organ furnished a product of "internal secretion" which causes in the pancreas the transformation of its inert zymogen into active trypsin.

I shall, in conclusion, briefly examine the criticisms to which the researches of Schiff and Herzen have been exposed. It is not proposed to consider objections purely speculative and theoretical, since, however plausible the arguments of such may appear, they cannot be brought into the same *category* with established facts; I shall therefore concern myself only with those having at least the semblance of being supported upon an experimental basis; and even in these cases it will be apparent with what lightness of heart the critics of Schiff and Herzen have undertaken their task—a lightness of *heart* only *equalled* by that of a large number of physiologists who have given these criticisms their support. Now the first rule required to be observed in endeavouring to test the results of a particular line of research consists in the exact reproduction of the original fact which it is sought to establish, a proceeding only rendered possible by the second observer reproducing accurately the experimental conditions under which the first laboured. Having done this the way is then open *for him to repeat* the several experiments, modifying them in what way he will in order to detect in them possible sources of error. This elementary rule appears to have been entirely overlooked by the opponents of Schiff and Herzen, as will readily be gathered from the following examples of their *modus operandi*.

In 1868 the Italian physiologist Lussana extirpated the spleen in three dogs and killed them later in order to ascertain whether the extract of their pancreas would digest coagulated albumin. One of his dogs suffered from a chronic peritonitis, another from an inflammatory condition of the pancreas. The pancreatic infusion from these two animals digested minimal quantities of albumin (maximum 0 25 gramme) in 24 hours. The third dog appears to have been healthy and its *pancreas* digested 1·10 grammes. The animal had, however, been killed three hours after a meal—i.e., at a moment when, even had it been in possession of its spleen, that organ would not yet have commenced to become congested. The experiment, therefore, gave the result which might be expected—viz., no digestion, *for nobody would accept seriously the digestion* of 1·10 grammes, knowing that the pancreas of a dog when digesting can dissolve from 50 to 60 grammes of albumin, for which, however, it is not only necessary that the spleen should be intact but also that it should be maximally congested, a phenomenon only commencing from six to seven hours after a meal. Nevertheless, Lussana concluded that in the absence of the spleen the pancreas digests just as well as when it is present, and that the diseased pancreas losing its *peptonising property* it *was* natural that Schiff had not found this property "*chez ses lapins dératés.*" It would seem evident that not only had Lussana never seen a true digestion by an active pancreas, but also that he had never read the work which he professed to criticise. This, however, did not prevent the majority of physiologists from blindly accepting his conclusions and declaring that the hypothesis of Schiff had been unable to withstand experimental proof, and in spite of the fact that Herzen, then Schiff's assistant, had immediately issued a severe analysis of Lussana's publication, to which, however, the latter never replied. For 10 years after Lussana's statement continued to be made, the name of Herzen being now coupled with that of Schiff, without the least attempt at experimental inquiry, Herzen published later an account of his own researches, the equally surprising results of which, obtained by an altogether new method, entirely confirmed those of Schiff.

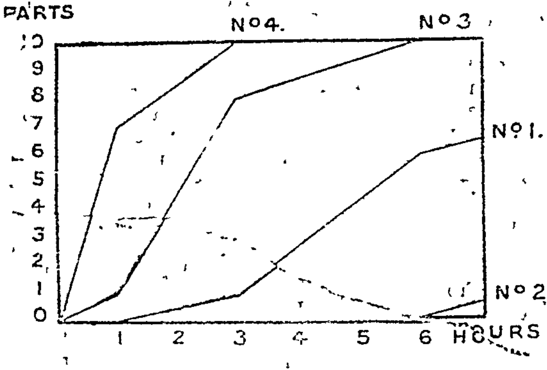
In 1893 two French observers, Carvallo and Pachon, communicated to the Société de Biologie, and also published in the *Archives de Physiologie*, an account of some experiments said to be performed according to Herzen's method *and of which the results were entirely negative.* One would again be inclined to ask whether the authors had read the work which they undertook to criticise, for they, like Lussana, altogether neglected the conditions most essential to the experiment. Owing to too prolonged extraction they allowed a large part of the zymogen to become transformed into trypsin before even comm [illegible] ments, and in the course of [illegible] the transformation of the [illegible] allowed to take place, so that in summing up their results they were unable to perceive any difference in the activity of their infusions. Herzen replied by drawing the attention of the authors to this double source of error which deprived their experiments of all value. Pachon, now professor of physiology at *Bordeaux, fully comprehended* the gravity of these errors and resolved to do now what might reasonably have been expected of him and his colleague in the first instance—conscientiously to repeat the experiments of Schiff and Herzen by conforming to their directions; the result was that Pachon confirmed all their results and, together with his new collaborator Gachet, was entirely won over to their point of view. Nay, they did more, they invented an entirely new experiment, at once original and *ingenious*, which consisted in realising *in vivo* what Herzen had hitherto only done *in vitro.* This experiment was as follows.

A dog, which a long time previously had undergone splenectomy, was anæsthetised and half its pancreas was removed and immediately *infused; at the same time* a normal dog, in the height of digestion, was killed and its congested spleen was infused in water and this infusion was injected *into* the venous system of the spleenless dog; *from* 15 to 20 minutes afterwards the remaining half of the pancreas of the latter dog was infused *exactly* like the first; of the two infusions when given fibrin or albumin, the second only digested rapidly and copiously.

It would be thought that after proof so absolute the *doctrine* thus established by six different methods, first by Schiff and Herzen and afterwards by Pachon and Gachet, would enjoy immunity *from* attacks so reckless as the preceding. Such, however, was not to be the case, for last year a Russian observer, Popelski, conducted a series of experiments in which *he succeeded* in combining the *error* of Lussana with those initially made by Pachon in conjunction with Carvallo. In both normal and splenectomised cats he collected the pancreatic juice by means of a cannula introduced into the duct of the gland, and was

The following charts graphically illustrate the quality of the results obtained in the case of fibrin. The albumin digestions are omitted, since, being necessarily so slow, they show but imperfectly the influence of the splenic infusions in bringing about rapid and copious digestion quite independently of spontaneous transformation of the zymogen. For the same reason the time of observation is restricted to six hours. The numbering of the curves in these charts corresponds to that of the liquids in the account of the experiment.

Chart 1.



An ordinary digestion in which the fibrin to be digested is considered to be divided into 10 equal parts, the curves showing the number of such parts digested in the time-limits figured on the base line. Notice the immediate and copious digestion under the influence of the splenic infusions and that No 2 is barely commencing to digest even after six hours.

In these experiments the enormous acceleration in the digestion of the fibrin under the influence of the two splenic infusions is very evident. As for the albumin it only digests in an appreciable manner when under this influence; the activity of No. 4 may give rise to the suspicion that it was due to the neutralisation of the boric pancreatic infusion by the aqueous splenic infusion. To this objection, however, No. 3 conveys a sufficient reply.

In many of Herzen's experiments the digestion performed by the mixture of the two infusions has been still very much more rapid. He has, in fact, sometimes seen the initial dose of fibrin totally disappear at the end of the first hour. In these cases a second dose of fibrin added by him disappeared in its turn before the third hour. This activity in the digestion of the fibrin was also accompanied by a corresponding acceleration in that of the albumin. The latter, however, was rarely entirely dissolved even after 24 hours. This substance has therefore never given the enormous differences yielded by the fibrin which liquefies extremely rapidly in contact with trypsin. It would be difficult to obtain in a series of experiments a harmony more complete or a sequence more natural upon the researches of Schiff [illegible] Herzen therefore believes himself justified [illegible] he living pancreas the trypsinogen [illegible] o active trypsin under the influence [illegible] in the spleen, in a quantity propo[illegible] Strasburg in [illegible] contain-ing [illegible] er of his digestions, the digesting liquid having been decanted and replaced by alcohol. [illegible] examined them all recognised that th[illegible] the residua left by the pancreatic [illegible] those of the mixtures of the pancreatic and splenic infusions were very [illegible] conversation with Herzen, how[illegible] following criticism. It is well [illegible] reatic zymogen is very greedy of oxygen; on the other hand, the spleen during its dilatation is engorged with blood. The splenic infusions exhibited were intensely coloured by dissolved hæmoglobin—*ergo*, the undoubted and considerable acceleration in digestion obtained by adding such a liquid to another containing trypsinogen could be quite simply explained by the rapid oxidation of the zymogen at the expense of the hæmoglobin. This objection disconcerted Herzen in no inconsiderable degree and he lost no time in making it the subject of experimental inquiry. An exceedingly active digestion in which the whole of the second dose of 10 parts of fibrin has been digested by No. 4 in three hours. Corresponding activity in unmixed infusions. No second dose was added to No. 3, the initial dose of which had been entirely dissolved at the end of three hours.

the digesting animal. The result of the experiment was as follows. After one hour there was still no trace of digestion under [illegible] blood, arterial or venous, nor of [illegible] of the fasting dog; first traces [illegible]ing to manifest themselves under [illegible]enic venous blood of this animal. Digestion was rather advanced in the case of the femoral arterial and venous blood and splenic arterial blood of the digesting dog; the fibrin had almost entirely disappeared under the influence of the splenic venous blood of the same animal.

The answer could not be clearer: the product of the internal secretion of the spleen, borne therefrom by the circulating blood, is present during the period of the dilatation of the spleen in feeble but appreciable quantity in the blood of the general circulation and abundantly in the splenic venous blood. The venous blood returning from the contracted spleen only contains it in very small quantities. This experiment, several times repeated, always gave the same result, showing that it is not the blood as such which favours the transformation of pancreatic zymogen into trypsin, but that, by picking up from the spleen the unknown substance possessing this property, the blood becomes its vehicle and means of communication with the pancreas.

At the International Congress of Physiologists, held at Berne in 1895, Herzen exhibited a second series of specimens preserved as an objective document of results arrived at by another method in which use was made of concentrated glycerine infusions. Under these conditions digestion is extremely slow even in the case of fibrin; even should the liquid already contain trypsin but little diminution of the fibrin can be observed after the lapse of several days, and at the same time an effective check is put upon the spontaneous transformation of the zymogen into trypsin. In the infusion of the pancreas alone the fibrin maintains indefinitely its original bulk; in the mixture of the two infusions it gradually dissolves and finishes at the end of three or four weeks by disappearing altogether. The specimens shown by Herzen at this Congress were already one year old. I have seen others in his laboratory at Lausanne which have been preserved for six years, forming, together with those originally exhibited at Strasburg, a striking object-lesson for those following his teaching.

From the bulk of evidence collected by Herzen there thus seems to be very little room for doubt that apart from hæmatopoietic, and possibly allied, functions possessed by the spleen, the organ furnished a product of "internal secretion" which causes in the pancreas the transformation of its inert zymogen into active trypsin.

I shall, in conclusion, briefly examine the criticisms to which the researches of Schiff and Herzen have been exposed. It is not proposed to consider objections purely speculative and theoretical, since, however plausible the arguments of such may appear, they cannot be brought into the same category with established facts; I shall therefore concern myself only with those having at least the semblance of being supported upon an experimental basis; and even in these cases it will be apparent with what lightness of heart the critics of Schiff and Herzen have undertaken their task—a lightness of heart only equalled by that of a large number of physiologists who have given these criticisms their support. Now the first rule required to be observed in endeavouring to test the results of a particular line of research consists in the exact reproduction of the original fact which it is sought to establish, a proceeding only rendered possible by the second observer reproducing accurately the experimental conditions under which the first laboured. Having done this the way is then open for him to repeat the several experiments, modifying them in what way he will in order to detect in them possible sources of error. This elementary rule appears to have been entirely overlooked by the opponents of Schiff and Herzen, as will readily be gathered from the following examples of their *modus operandi*.

In 1868 the Italian physiologist Lussana extirpated the spleen in three dogs and killed them later in order to ascertain whether the extract of their pancreas would digest coagulated albumin. One of his dogs suffered from a chronic peritonitis, another from an inflammatory condition of the pancreas. The pancreatic infusion from these two animals digested minimal quantities of albumin (maximum 0·25 gramme) in 24 hours. The third dog appears to have been healthy and its pancreas digested 1·10 grammes. The animal had, however, been killed three hours after a meal—i.e., at a moment when, even had it been in possession of its spleen, that organ would not yet have commenced to become congested. The experiment, therefore, gave the result which might be expected—viz., no digestion, for nobody would accept seriously the digestion of 1·10 grammes, knowing that the pancreas of a dog when digesting can dissolve from 50 to 60 grammes of albumin, for which, however, it is not only necessary that the spleen should be intact but also that it should be maximally congested, a phenomenon only commencing from six to seven hours after a meal. Nevertheless, Lussana concluded that *in the absence of the spleen the pancreas digests just as well as when it is present*, and that the diseased pancreas losing its peptonising property it was natural that Schiff had not found this property "*chez ses lapins dératés.*" It would seem evident that not only had Lussana never seen a *true digestion* by an active pancreas, but also that he had never read the work which he professed to criticise. This, however, did not prevent the majority of physiologists from blindly accepting his conclusions and declaring that the hypothesis of Schiff had been unable to withstand experimental proof, and in spite of the fact that Herzen, then Schiff's assistant, had immediately issued a severe analysis of Lussana's publication, to which, however, the latter never replied. For 10 years after Lussana's statement continued to be made, the name of Herzen being now coupled with that of Schiff, without the least attempt at experimental inquiry, Herzen published later an account of his own researches, the equally surprising results of which, obtained by an altogether new method, entirely confirmed those of Schiff.

In 1893 two French observers, Carvallo and Pachon, communicated to the Société de Biologie, and also published in the *Archives de Physiologie*, an account of some experiments said to be performed according to Herzen's method and of which the results were entirely negative. One would again be inclined to ask whether the authors had read the work which they undertook [illegible] Lussana, altogether neglected th[illegible] to the experiment. Owing to too [illegible] allowed a large part of the zymogen to become transformed into trypsin before even [illegible] ments, and in the cour[illegible] the transformation of [illegible] allowed to take place, so that in summing up their results they were unable to perceive any difference in the activity of their infusions. Herzen replied by drawing the attention of the authors to this double source of error which deprived their experiments of all value. Pachon, now professor of physiology at Bordeaux, fully comprehended the gravity of these errors and resolved to do now what might reasonably have been expected of him and his colleague in the first instance—conscientiously to repeat the experiments of Schiff and Herzen by conforming to their directions; the result was that Pachon confirmed all their results and, together with his new collaborator Gachet, was entirely won over to their point of view. Nay, they did more, they invented an entirely new experiment, at once original and ingenious, which consisted in realising *in vivo* what Herzen had hitherto only done *in vitro*. This experiment was as follows.

A dog, which a long time previously had undergone splenectomy, was anæsthetised and half its pancreas was removed and immediately infused; at the same time a normal dog, in the height of digestion, was killed and its congested spleen was infused in water and this infusion was injected into the venous system of the spleenless dog; from 15 to 20 minutes afterwards the remaining half of the pancreas of the latter dog was infused exactly like the first; of the *two infusions* when given fibrin or albumin, the second only digested rapidly and copiously.

It would be thought that after proof so absolute the doctrine thus established by six different methods, first by Schiff and Herzen and afterwards by Pachon and Gachet, would enjoy *immunity from* attacks so reckless as the preceding. Such, however, was not to be the case, for last year a Russian observer, Popelski, conducted a series of experiments in which he succeeded in combining the error of Lussana with those initially made by Pachon in conjunction with Carvallo. In both normal and splenectomised cats he collected the pancreatic juice by means of a cannula introduced into the duct of the gland, and was unable to find any difference in digestive activity. As, however, his cats had been fasting since the day before, his experiments were made outside the digestive period during which the spleen, becoming congested, furnishes abundantly its product of internal secretion which transforms rapidly and copiously the zymogen into trypsin. The experiments, therefore, of this observer are totally devoid of all value and it is useless to enter into further details concerning them, only observing that even had their author taken careful note of the conditions under which occurred the fact he purposed to check, his experiments would still have been incapable of demonstrating the differential digestion, seeing that being conducted with albumin only they were necessarily very much too prolonged; the whole affair, in short, was carried out in such a manner that not only was the fundamental fact wanting but even had it been present its recognition would have been impossible. But Popelski also performed some analogous experiments on a dog with a permanent pancreatic fistula made according to the method of Pavloff. The pancreatic juice of this animal was several times collected and examined before and after splenectomy without any difference in activity being demonstrable; this result, however, elicits no surprise in view of the fact that in both instances the juice was always collected immediately after a meal—i e., again to repeat it, in advance of that digestive period during which the spleen enters into function and the pancreas abounds in trypsin, so that, as well in this experiment as in that with his cats, Popelski was placed in that position in which the presence or absence of the spleen was a matter of perfect indifference—a fact, however, which does not deter him from declaring with perfect assurance and manifest self-satisfaction that the theory of Schiff, Herzen, Pachon, and Gachet is based upon defective methods and should be rejected. Popelski does not thus even seem to have perceived that it is no longer a question of theory but of facts—facts which if he wishes to control he must observe in those conditions under which they occur, and of which it is absurd to deny the existence because they do not occur outside these conditions; in fact, Popelski, to quote Herzen's own words, is in the position of the astronomer who, knowing that a solar eclipse will occur on a certain date, deliberately looks for its appearance on the day previously to that date.

Such is the blind and thoughtless nature, truly extraordinary, of the criticisms passed upon the work of those who by the patient and persevering work of long years have discovered, tested, confirmed, and definitely established the importance of the rôle played by the spleen in the production of trypsin. Those who have intimately studied their works remain firmly convinced of the validity of their results and believe that but few physiological facts are more irrefutably established.

It has been stated earlier in this article that the organism as a whole apparently suffers no disadvantage from removal of the spleen. What, however, in the light of Herzen's results is the actual loss suffered by such an organism? The answer is clear—almost complete cessation of proteid digestion by the pancreas, this function being in such cases almost entirely performed by the stomach. But the zymogen which the pancreas continues to elaborate, does it become entirely lost, or does it continue to serve some useful purpose in the organism? A possible reply to this question might be that the zymogen being excreted as such becomes gradually transformed into trypsin by oxidation or other agency along the intestinal tract. The possibility of this explanation seems to have been suggested to Schiff and Herzen by an observation accidentally made in cases of duodenal fistula, according to which it appeared that pieces of albumin enclosed in fibrous membrane introduced into the living duodenum of splenectomised animals would become more or less digested if the thread fixing the arrangement to the cannula happened to be made too long, thus allowing the bag and its contents to wander further along towards the jejunum. The experiments of Popelski seem also to be a strong hint in the same direction by showing that the pancreas even of fasting animals will very slowly digest more or less proteid. Why, however, in these cases does the general nutrition of the animal not appreciably suffer? Is the peptonising power of the stomach, coupled with such slight assistance as may be derived from the pancreas in the manner just mentioned, sufficient for the ordinary needs of the body? It is a well-known fact that most animals eat too much, thus involving a certain superfluity not only of material consumed but also of digestive activity in both the stomach and the pancreas. On the other hand, it has been noticed and even confirmed by Schiff that spleenless animals require more food than intact animals, a fact which could find its explanation not only in the loss of direct peptonising surface in the alimentary tract, but also in that the parapeptones normally going on to the duodenum to be converted into true peptone by the pancreatic juice, are, owing to the breakdown of the pancreas, no longer capable of being absorbed and assimilated by the organism. The stomach and pancreas, in as far as the digestion of proteids is concerned, would then appear not only to work in perfect unison with one another in the intact organism, but when through any cause whatever the one or the other is thrown out of action, its work is assumed and efficiently carried on by the survivor.

Lausanne.

SOME REMARKABLE CASES OF SARCOMA.[1]

BY A. MARMADUKE SHEILD, M.B. CANTAB.,
F.R.C.S. ENG.,
SURGEON TO ST. GEORGE'S HOSPITAL.

FOR many years surgeons have dwelt upon the sources of error and doubt which attend the diagnosis of sarcoma. The following case, one of suppuration in connexion with sarcoma, illustrates very forcibly the almost insuperable difficulties that may occur even when elaborate pains and care are taken and all modern methods of investigation are employed.

CASE 1.—In March, 1899, I saw, at a distance from London, with Dr. James Andrews of Hampstead, a man, aged about 40 years, who had lived hard but had never suffered from syphilis. A dubious tumour of large size had gradually developed towards the lower third of the left thigh. This formation had been noticed for about six months as beginning as a "thickening" about the lower third of the shaft of the femur. No cause was assigned for it. There was an obscure history of a blow on the part four years before. Iodides were given in full doses and strapping and mercurial ointment were employed without avail. Shortly before I was called in an exploratory incision had been made by a surgeon into the outer side of the swelling; nothing but blood escaped, and the diagnosis of sarcoma was arrived at. When I saw the patient late at night in company with several other medical men, he was somewhat relieved from the very significant circumstance that pus had escaped from the wound. Previously for several days he had been ill and delirious, with considerable fever. I found him to be a well-developed man, ill and feverish, with a dry tongue and all the signs of septic infection. The lower third of the left thigh was occupied by a large, somewhat fusiform, tumour of the size of a big pumpkin which had all the aspect of a soft sarcoma. But the skin over it was red, it was hot to the touch, and, moreover, it felt elastic and fluctuated in all directions with great distinctness. I at once mentioned my doubts as to whether the case was one of inflamed sarcoma or abscess and advised that another exploratory incision should be made, and that if the case turned out to be sarcoma amputation should not be performed in the present inflamed and septic state of the thigh. This was agreed upon and was carried out on the following morning. Dr. M. Parry-Jones of Alfreton gave an anæsthetic and Mr. H. G. P. Le Fanu of Derby and Dr. James Andrews were present and assisted. The previous incision was enlarged and my finger at once entered a large cavity. On withdrawing the finger a gush of pus took place, the amount of which was not measured, but it filled a bowl of considerable size. I made a counter opening on the inner side just above the knee and evacuated more pus. The shaft of the femur was bare of muscles for some four or five inches, but not denuded of periosteum. The patella and the capsule of the knee could be felt, the great abscess being evidently quite extra articular but beneath the quadriceps tendon. The movements of the knee were free. The walls of the large cavity were thick and definite, but no trace of growth could be felt. Full-size tubes were inserted, and the cavity was well flushed out. I expected that this abscess must have depended upon necrosis of the femur, and the obscure history of an injury some four years before lent some colour [illegible] ever, [illegible] ower [illegible]. I, however, dismissed the diagnosis of sarcoma, and expressed the opinion that the case was one of deeply-seated abscess round the femur and that the cause was obscure. I believed the case would do well. How erroneous this opinion proved subsequent events will show. A few days after the operation there was a return of fever and pain This was due to some slight retention of discharge and it soon passed away. The tubes were [illegible] shortened by Dr. Parry-Jone [illegible] to the case and gave me m [illegible] discharge always remained scanty and the wounds were nearly closed about the middle of April. The patient all this time had lost his fever and had put on some flesh and he looked better than when I had opened his abscess Indeed, the case had behaved quite consistently with the progress of a suppurative affection. About the middle of April Dr. Parry-Jones suspected that the case was not so simple, as a distinct mass had again begun to form, the swelling assuming much of its old aspect and the discharge being very scanty. A portion of tissue from one of the sinuses was examined and the microscopical report, as is occasionally the case, was favourable but sadly misleading. It stated definitely that there was vascular granulation tissue but no evidence of malignant disease About this time I wrote and suggested that the discharge should be examined for actinomyces, but this had already been done. The patient came to town early in May when I examined him. The swelling was as large as ever. The wounds had practically healed Very distinct fluctuation could be obtained on either side and the temperature was raised at nights. I expressed the opinion that the previous drainage had been insufficient and I thought the whole cavity should be laid open along the outer side, cutting through the vastus externus muscle. I expected to find much inflammatory material and a sequestrum. Before undertaking so extensive an operation I desired another opinion, and Mr. Frederick Treves saw the patient with Dr. James Andrews and myself early in May. He was at once struck with the resemblance of the case to one of actinomycosis, and suggested that the discharge should be carefully examined for the ray fungus. He suggested free opening and curetting with patient and prolonged flushing and subsequent gauze tamponade. I operated two days after, Dr. James Andrews and Dr. E Collingwood Andrews kindly [illegible]

huge cavity had practically been converted into an abscess. The evacuation of so large a quantity of pus was exceedingly misleading, and explained a diagnostic error which, under the circumstances, was perhaps almost unavoidable and I believe would have been made by any surgeon. Amputation at or near the hip was now the sole resource I did not urge it as the case in all respects was very unfavourable, and the fear of leaving infected flaps could not be laid aside All further treatment was refused. The growth rapidly extended and the patient died from exhaustion in July, 1899 An early amputation, prior to any septic action in the thigh, might perhaps have saved him for a time. I have thought it right to publish this case because it carries with it much useful instruction. I believe that any surgeon who had seen it would have fallen into error and pronounced it undoubtedly inflammatory. I think it one of the most striking cases which I have ever seen and one which illustrates the extremes of caution with which we should deal with such cases from a prognostic and diagnostic point of view.

CASE 2.—The second case was one of ulceration of the toe, followed by melanosis of glands in the groin. Through the kindness of Dr. B. R. Martin of Hammersmith I saw in January, 1899, a man, aged 49 years. For about 12 months the fourth toe on the right foot had given him trouble. He attributed this to the fact that a corn had formed underneath it, and that he rubbed this with his boot. Anyhow, an obstinate ulcer formed on the plantar surface of the toe and refused to heal. On examination an oval ulcer with irregular margins was seen to occupy the under surface of the toe; it was deep and nearly exposed the tendon. The base was covered with pale granulations and the edges were "heaped up"; they were white and callous, exactly like the tissues of a "corn" which indeed I opined it to be. The toe was amputated, the wound healed in a few days, and the patient left my care much relieved in walking. In April he came and showed me an enlarged gland of about the size of a filbert in Scarpa's triangle. This had been noticed accidentally. The swelling was moveable and elastic, and at one spot the sensation of fluid was evident. I believed this swelling to be a suppurating gland; but the possibility of a new growth entered my mind, and I urged upon the patie [illegible] the lump at once explored by [illegible], this advice was declined. Oth [illegible] the patient, largely swayed by the advice of irresponsible relations, allowed his case to take care of itself. I saw him from time to time, and fluctuation was so evident in the increasing swelling that the diagnosis of a chronic abscess seemed more and more certain. The thought of inserting an exploring syringe was not absent, but I feared to do this to a possible soft growth unless I had permission to proceed at once to operation. In May the swelling had increased to the size of a small orange, and had commenced to cause grievous pains down the course of the crural nerves. I now felt that there was ground for serious alarm, and I spoke very strongly to the patient regarding his grave condition. He entered the "pay wards" of Guy's Hospital and was operated upon by Mr. L. A. Dunn who kindly informed me that the swelling in his groin was a soft melanotic growth. This result much astonished me for I had looked at the toe very critically, and I feel sure, having seen several of these most deceptive cases, that any blue or black discolouration would have [illegible] I presumed that the extensiv [illegible] otic nodule in the toe had obl [illegible] acters of the disease. I have lately heard that this patient, as usual, succumbed to a general dissemination of the disease.

CASE 3.—This was a case of sarcoma of the tibia simulating an abscess. A married woman, aged 41 years, had obscure pains in the right leg for about three months. The site of greatest severity was near the right knee on the inner side She was a healthy-looking woman, all her bodily functions were well performed, and there was no evidence of syphilis There was a diffused and hard swelling on the inner side of the tibia just below the knee. This was a little red, hot, and exquisitely tender. Indeed, the symptoms were those of a localised periostitis and osteitis of a somewhat acute nature The patient was admitted into St. George's Hospital on July 29th, 1899, and was placed on large doses of iodides The pains were not relieved, and by the middle of August there was a fluctuating swelling of the size of a pigeon's egg over the tibia. Indeed, the diagnosis of abscess probably associated with necrosis seemed very certain. On August 19th, the swelling was opened by the house-surgeon under the supposition that it was an abscess. I may relate exactly what occurred, as it more forcibly illustrates the extremely interesting lesson which this case teaches. Being present, I remarked: "Do not lay that open at once, but make a puncture into it to be sure of your diagnosis Some of these swellings turn out to be soft sarcomata, and if you lay these freely open you will land yourself in disaster." He replied, "I do not think this is anything of the kind, but make the puncture" This was accordingly done with a fine knife, and instantly a jet of blood shot up to the height of several inches, slightly rising and falling with an ill-marked pulsation. The picture was one which no one who saw it could ever forget. I closed the puncture by a deep suture, put on pressure, and prepared the patient on the next day for a possible amputation should this be needful. On the 24th Esmarch's apparatus was applied and I turned up a quadrilateral flap over the site of mischief. A soft sarcomatous growth of the size of a small orange was disclosed, and it came through the compact tissue of the tibia by a curiously circumscribed hole which looked as though made by a trephine. This was obviously only part of a much more serious complication of the interior of the bone, and I therefore amputated in the lower third of the thigh, the patient making a good recovery. Dr. W. S. Lazarus-Barlow kindly examined the specimen and reported that the growth was sarcomatous and of the nature of so called myeloid disease and that it had originated in the medullary tissue of the tibia. A serious mistake was avoided in this case by a precaution which may well have seemed to be superfluous, and the timely establishment of the diagnosis may perhaps serve to re-establish the blemished reputation which the relation of the first case may have aroused in the minds of my audience!

CASE 4.—The last case I am about to relate is one of surpassing interest, especially to my medical *confrères*. In the year 1898, I saw a strong, robust-looking man, aged about 40 years. For six months he had been ailing, with vague pains about the back and the left side, and especially he complained of severe shooting pains down the left thigh and over the buttock. He had seen several physicians, as well as general practitioners of standing and sagacity. The consensus of opinion had been in favour of rheumatism, and he had gone abroad and taken "waters" without benefit. I have no doubt that diagnosis was really quite impossible at this early period of his case. On examining him I was struck with some enlarged veins over the left side of the abdominal wall, and on deep palpation a hard, irregular, and fixed mass could be felt under the left false ribs, close to the side of the spine. I watched the case for some weeks, though I was much pressed for an immediate opinion, and next it was noted that there was an irregular nocturnal rise of temperature, and I began to fear that the case was one of spinal disease with deep abscess. One day, however, the patient drew my attention to a swelling of the left testis, which he said he had suffered from since the onset of his symptoms. Moreover, the testis had gradually become larger. On examining the organ i[illegible] an enlargement affecting the body [illegible] and on carefully palpating the cord some masses could plainly be felt towards the inguinal region. Though no history of syphilis could be obtained the patient was placed on full doses of iodide of potassium, but though he continued the remedy for some weeks no result was obtained. The mass in the belly got more evident and could especially be felt posteriorly and the pain was worse. I now gave an opinion that the case was one of retro-peritoneal sarcoma, secondary to a testicular growth. This was afterwards verified by Sir William Broadbent and others. The case ran the usual progressively fatal course. A remarkable feature in it was the nocturnal rising of the temperature, which averaged 101° F. and sometimes rose to 102° or 103°. Towards the end of life severe attacks of phlebitis and thrombosis occurred in the femoral and iliac veins, giving rise to agonising pain and necessitating the free use of narcotics. No necropsy was allowed, but huge masses of growth were evident at the end of life, pressing the intestines forwards, obviously retro-peritoneal and secondary to the growth in the testis.

These four cases are related as forcibly illustrating the extraordinary problems which the different varieties of malignant disease may present. Mistakes are hardly to be avoided even with the extremes of caution. As errors of judgment are well said to teach us more than successes I venture to bring the subject before you because I am aware that similar instances have occurred in the practice of others and that the subject is one of unsurpassed interest and importance as well as of extreme difficulty.

Cavendish place, W.

NOTIFICATION OF PHTHISIS.—At a meeting of the Bath Town Council held on Oct 15th Dr. W. H. Symons, the medical officer of health, proposed that the system of voluntary notification of phthisis which had been adopted in Manchester, Sheffield, Brighton, Stockport, Blackburn, Stonehouse, Plymouth, Kendal, Norwich, and Carlisle should be adopted in Bath. After some discussion the matter was referred to a sub-committee.

THE ANÆMIA OF DYSPEPSIA CONSEQUENT ON DIRT-EATING.

BY A. J. B. DUPREY, M.R.C.S. ENG., L.R.C.P. LOND.,
GOVERNMENT MEDICAL OFFICER, CARRIACOU, W.I.

HITHERTO in the disease known as ankylostomiasis attention has been given principally, if not altogether, to the expulsion of the parasites from the intestines, merely because they have been regarded as the root of all the evils attendant on the disease. It is the object of this communication to point out that, far from being the chief object in view, it is but the beginning of a long course of treatment requiring great patience, careful dieting, and strict supervision. In necropsies on subjects of ankylostomiasis one has but to consider the great numbers of those worms occupying the upper intestines to realise how inconsistent is the theory which seems to be the general opinion of the profession as regards the causation of the disease. To me the idea of blood-sucking ankylostomata is entirely out of the question, and I have always wondered how the anæmia so produced has not more speedily put an end to the patient's life sooner than is usual with these cases, for be it said that it is a disease which comes on very gradually, symptom after symptom manifesting itself, until the combination of such symptoms ends the trouble, often after a considerable period from the onset. After two years' observation of these cases both in hospital and district practice I have had constantly in mind the consideration of the probable cause, other than the parasites, of this progressive and fatal disease as we have it in this colony. A great deal has been said and written about ankylostomiasis as a disease, more care and attention being specially directed toward removal of the parasites from the intestines. Of course, there can be nothing said against that inasmuch as they must be, and are, a great source of discomfort to their hosts, but the important question as to the etiology of the disease in itself is lost sight of or not at all taken into consideration, and notwithstanding the undoubted relief obtained by the administration of anthelmintics patients do not recover so readily as would be expected. Presuming that the ankylostomata as forming the chief agents in causing a disease productive of such profound anæmia and its consequences act merely by the local abstraction of blood there would, I think, be no doubt as to the treatment; but in considering the parasites only as a secondary factor, a mere coincident symptom as I believe them to be, it is plain that their expulsion, though absolutely necessary and affording considerable relief, does by no means bring about a perfect cure. The name "ankylostomiasis" is obvious in its meaning and the theory of ankylostomata sucking blood from the mucous membrane of the intestines is comparable to a considerable quantity of minute leeches continually draining the patient of his life's blood, a most horrible idea in itself and a state of things under which the patient's life could not be expected to last any time. Then, again, it is most probable that instead of the local abstraction of blood, as is supposed to be the case, the parasites may feed upon the soluble products of digestion which would otherwise have been absorbed and carried to the tissues. Of the two the latter supposition would seem to be more likely the case, but even then one could suppose sufficient soluble products to be absorbed to keep up the nutrition of the body and that by getting rid of the parasites health would result after a due allowance of time. The name "ankylostomiasis" would still be justifiable, the disease originating, as it then would, directly from the parasites; but I do not think anyone who has the opportunity of observing the disease as it occurs here and in other countries can have any reasonable doubt about its being a malnutrition and not merely an anæmia due to hæmorrhage. The dyspepsia I take to be the primary and most important cause of the so called ankylostomiasis, though blood-sucking is so firmly believed in that it will be a matter of considerable difficulty to get anyone to give up the theory. According to various people it seems to be one and the same disease though known under different names. In this country the coolie labourers are by far the greatest sufferers, and not surprisingly so if only one considers their habits and manner of living. Their diet is very simple and meagre, they are for the most part vegetarians, but and get it they are made to take all. They are a people peas, curry, and ghee, this latter being a specially-prepared butter in great use among the race. This frugal diet to men who are hard workers in the canefiel sun cannot be conducive to And when, in addition, there is whether acquired as a vice or, which is most probable, for the purpose of economy, the result cannot be otherwise than disastrous. I have always connected the disease known as ankylostomiasis with the dirt-eating habit and with good reason, for I have frequently come across coolie patients with gravel hidden on their persons or actually caught them in the act of eating such dirt, and the craving is so strong that the coolie will cry and beg for the dirt which he so much cherishes. This is generally a soft slate-coloured or greyish stone which is very much in use among them or sometimes it is the actual dirt made into cakes and not unfrequently rags, paper, and coke are eaten. On this account there is a considerable loss of labour yearly. Owners of immigrants have been aroused to the fact that the disease is greatly on the increase and are much embarrassed by the large number of disabled coolies. The result arising from such a habit is obvious and the hospitals, both those of the districts and the estates, are crowded with sick coolies The anæmia, which I take to be the direct outcome of such a prolonged and inveterate habit, is the cause of the greatest percentage of hospital patients, and though there must be no inconsiderable difficulty in effectually checking the habit, yet attempts might be made even to minimise this vastly increasing scourge.

There is no difficulty in recognising the advanced disease which to those accustomed to deal with it is diagnosed from merely looking at the patient. His appearance is characteristic, he is much swollen generally, his face is puffy and has a distressing look which seems to invite your attention to his hopeless condition, he walks into the surgery with slow and measured steps and shows you his legs which are swollen and tense with œdema, and he complains of pain in the whole body. There is a look of weariness and premature agedness about him which is marked; he has shortness of breath and is unable to speak but makes signs to indicate his distress. When asked to put out his tongue he opens his mouth, disclosing the organ lying in the floor of the mouth, and if urged to protrude it does so with great difficulty, purely from weakness. The tongue is shockingly anæmic, large, swollen, and flabby, and strongly marked by impressions of the teeth The conjunctivæ are exsanguine; the patient complains of severe headache, dimness of sight, and not unfrequently diarrhœa and pains in the abdomen. The incipient disease, however, is not so easily recognised and some care is necessary to arrive at a correct conclusion A patient will of course, never reveal that he is a dirt-eater and very strongly denies the fact, though if searched at the moment evidence might be found on his person of his doing so He is young, mostly between 20 and 30 years of age, and to all appearances is in good health. He complains of pain in his legs and all over his skin, of shortness of breath on exertion, and pain in the pit of the stomach. There is no marked anæmia or any of those symptoms mentioned above; he is apt to be put down as a malingerer and treated accordingly, even sometimes prosecuted and imprisoned. The physical examination of his chest reveals nothing as a rule, with the exception perhaps of a slight hæmic bruit along the left edge of the sternum There is one sign, however, which seems to be very constant among dirt-eaters, it matters not of what age, and that, one of the earliest indications of a malnutrition, is the condition of the skin This, I believe, to be a great point in helping one to arrive at the true state of things in the early disease If the skin of the face is pinched up between the index finger and thumb it is felt at once to be different from that of the healthy individual—it is thin, flabby, and lacking in firmness, and has somewhat the same feeling one experiences in pinching up the skin of an aged person; the atrophy and loss in tone are unmistakable This is a sign which is noticeable even in young children who are addicted to the habit. It is a symptom which might be thought peculiar to wasting diseases generally, but whereas in other diseases there are sure to be other symptoms more or less advanced to account for the malnutrition, here it is the commencement of the trouble, and no other cause can be found or assigned to it. Such a patient is put on the thymol treatment, and very put on an iron mixture, which is very wrong, so that no consideration is taken at all of the condition of the mucous membrane of his stomach. Often he is put on a diet which he is quite incapable of digesting, as is proved by the fact that one sees occasionally a whole meal passed in the stools almost unchanged. It is not to be supposed that a habit such as I describe, probably of many years' standing, can have had no ill effect on the physiological function of such an important organ as the stomach. Digestion suffers and the blood and tissues starve accordingly. The symptoms of anæmia and malnutrition increase gradually, the patient gets into a condition of hydræmia, and so from bad to worse until he gets into a state well-nigh incurable and eventually dies from heart failure, mere poorness of the blood, or exhausting diarrhœa. Diarrhœa in such cases is a very bad sign and one which indicates that the end is not far off or, at all events, that recovery is hopeless. It is not produced, as is supposed, by irritation due to ankylostomata, but it is partly the safety-valve action of the mucous membrane in relieving a serum-soaked system and partly the result of irritation from indigestible and decomposed food-stuffs. Post mortem examination shows extreme anæmia and degeneration of all the organs, with hydro-pericardium, hydro-thorax, and ascites; the stomach is always dilated, sometimes to a considerable extent—not the dilatation of obstructive pyloric disease but a uniform dilatation; its mucous membrane is atrophied. The intestines are atrophied and there may or may not be ankylostomata. All these signs seem to me to be brought about by a gradual abuse of the powers of digestion time. Taken in time the habit o tion of dirt into the stomach in sequent dyspepsia should form the main point to which we should direct our efforts. The disregard the intestinal paras them is the first step of the t not infrequent where all the symptoms of this form of anæmia are present and not even the most careful administration of thymol will bring away any worms. The presumption, therefore, is that there are none I remember one such case in a boy of dirt-eater and i improved consic watched very closely. He did very well and his formerly pasty complexion had just began to assume the colour of health when he left my care. A couple of months afterwards I saw him in the diarrhœa ward where he died with violent purging. What happened was that the watch kept on him was relaxed and he soon fell into his old habits again. At the post-mortem examination I failed to find any ankylostomata, though I looked for them very carefully. Finally, I will mention the case of a man who is now under my care and who, though he has not got the habit of eating dirt, nevertheless follows a calling highly favourable to the ingestion of earthy matters into the alimentary canal. He is a labourer on a cocoa estate and as such has his hands more or less constantly encrusted with the soil six days out of the seven, and in the hurry of his work seldom thinks of washing his hands. It is the usual thing with such labourers and the dirt is thus taken into the stomach during meal time. In addition the man's food was very bad, consisting principally of salt fish which was certainly not of the best. He had thymol administered twice in the space of a fortnight and only on the first occasion were ankylostomata found and these were not many. He is a Spaniard, 24 years of age, under treatment for shortness of breath and swelling. He is very anæmic and swollen, his face is bloated, and the skin when pinched up is loose, flabby, and wanting in elasticity The lungs are free, the heart area is normal, and a systolic bruit is heard. The urine is normal. The point of interest is that though his anæmia is fairly advanced there does not seem to be any remarkable quantity of the parasites in the intestines sufficient to produce the anæmia There are many cases where ankylostomata are not to be found at all, notwithstanding the care taken both in the administration of thymol and the straining of the motions. Moreover, a patient may be chosen for experimental purposes who has not the least symptom of anæmia and thymol given in the ordinary way and ankylostomata demonstrated sometimes to a considerable extent. In such cases the parasites are taken in drinking-water and do not seem to affect their hosts in the least.

Carriacou, W.I.

THE DIFFERENTIAL DIAGNOSIS IN GENERAL PRACTICE OF PLAGUE AND TYPHOID FEVER.

By THOMAS COLVIN, M.B., C.M. Glasg.,
LATE PHYSICIAN TO THE GLASGOW CENTRAL DISPENSARY; LATE EXTRA PHYSICIAN TO THE GLASGOW VICTORIA INFIRMARY DISPENSARY.

It is evident that the early diagnosis and complete isolation of cases of plague are of supreme moment on account of their far-reaching results. As the Cardiff case as well as most of the Glasgow cases of plague have simulated an ill-defined type of typhoid or enteric—the term which I prefer to use—fever, I venture to submit the following note on these two diseases in the hope that it will enable the busy practitioner to arrive at an early and correct diagnosis of plague. I write from the point of view of a general practitioner, a portion of whose work is among people who from pecuniary considerations and ignorance expect you to make your diagnosis, no matter how difficult, on a first examination of a patient the dirt of whose skin may obscure any rash or mottling, and who may be lying in a room where sunlight seldom enters and where the artificial light is a paraffin lamp or a tallow candle. My remarks are based on the three Malloy cases, the first recognised Glasgow cases of plague, which were described in The Lancet of Sept. 8th, 1900, and the case of Rosina M——, which was described in The Lancet of Oct. 6th, 1900, p. 1040, as well as other Glasgow cases I have seen demonstrated by Dr. J. Brownlee in the wards of Belvidere Hospital. I am much indebted to the authoritative papers which I mention as references. I first discuss the symptoms and physical signs common to both diseases and then refer to a distinguishing feature of each disease.

Onset.—Three of my cases were ushered in suddenly with headache, nausea, vomiting, and general malaise. In one of them delirium set in at the onset and remained till his death seven days later, and in the fourth case there was a history of "raving" at the onset. In all forms of plague the two most common symptoms at the onset are headache and vomiting. In the cerebral type delirium and nervous symptoms predominate, while in the pneumonic form the most striking early symptom is a dyspnœa out of all proportion to the physical signs revealed on examination. The characteristic point of the onset in plague is that it is commonly sudden. In enteric fever the onset is, as a rule, insidious. The patient tells you that for a week, or perhaps a fortnight, he has been out of sorts. He has not been fit for his work and has no appetite. He has a dull pain in his head, is wakeful or dreamful at nights, and has a tired feeling, and a little cough. He is sure that he has a bad cold in his system which, if not speedily cured, will gradually lay him up. The whole history of the onset of enteric fever in an adult points to an insidious disease. It is only in children, or in adults whose vitality is too low to repel for any length of time the attack of the typhoid bacillus that we find a sudden onset. The extremely difficult cases would be a very mild case of enteric fever and a very mild case of plague. Fortunately in almost all the mild cases of plague buboes are present, and we can also call to our aid Widal's reaction to differentiate enteric fever.

Temperature.—When seen two days after the onset the temperature of one of my plague patients was 103° F., the temperature of another case three days after onset was 102°, the temperature in the third case also three days after onset was normal, while the temperature in the fourth case, which I saw for the first time 18 days after onset, was normal, but the medical man who was called in at the onset informed me that it was then 104°. As a rule, after the onset the temperature in plague goes up rapidly In severe cases it reaches its maximum in 24 hours, but more often on the second or third day. The degree varies between 101° and 106°. The amount of the rise is no test of the severity of the case, for in the most fatal cases the temperature may not rise above 101°. One of my patients whose temperature was 102° when I saw her late in the afternoon had the same temperature on admission to the hospital on the following day at noon. The day following this her morning and evening temperatures were respectively 102° and 101·8°, while the next day they were respectively 102° and 100 4°. The temperature fell during the succeeding day from 101 4° to 98·6° and the patient expressed herself as feeling much better. Now the important point about her morning and evening temperatures is that they were the converse of what we should find in a case of enteric fever. The characteristic of the temperature in enteric fever is its remission, falling in the morning and rising in the evening. Let me here make some practical remarks on temperatures indicating fever in general practice. When I find a child with a temperature with no evident cause to account for it and I suspect the fever is due to an infectious disease, I take the mother into my confidence and enlist her aid in isolating my patient till I am able to confirm my suspicions or to reject them as groundless. For example, if I suspect measles or scarlet fever and the child sleeps with two or three other children I ask the mother to put him in a cot by himself or in any temporary bed she can improvise. A common practice is for the child to sleep with his parents till he is better. If the case is in a densely populated street and the people will only pay for one visit, and there is a doubt between scarlet fever, measles, and rötheln, I agree with Dr. Goodhart that the public and not the patient ought to have the benefit of the doubt, and I notify it as scarlet fever. If the patient is an adult and I suspect enteric fever I try to get him not only a bed but, if possible, a room to himself. In all ill-defined fevered conditions I order the mother or wife to buy a pennyworth of permanganate of potassium crystals and I tell her how to make with them gallons of disinfecting fluid, warning her to keep the crystals in a safe corner away from children. I then tell her to sponge the patient with this fluid and warm water night and morning and also to use it for washing the utensils that the patient uses. I always find that the bed to himself and the sponging are gratefully welcomed by the patient. In a suspected case of enteric fever I tell the wife or mother to note the appearance of the motions as soon as they are passed and then to pour disinfecting fluid over them at once and to lose no time in emptying them down the water-closet. In cases of suspected enteric fever also if the people are too poor or, as is more often the case, too penurious to pay for the two visits in one day I make it a point of seeing my patient one day in the morning and the next day in the evening for the sake of comparing the morning and evening temperatures. The common practical teaching is that any fever in this country and in all non-malarial regions which persists longer than seven days with no discoverable disease to account for the pyrexia is most probably enteric. As my old and ever kind teacher Sir W. T. Gairdner points out in The Lancet of Oct. 13th, p. 1096, this does not mean that we are to wait for a whole week or perhaps a whole fortnight for the sole purpose of giving the disease a name and without attempting to isolate the patient or to notify the sanitary authorities. Why not at once—for our patient has probably been ill several days before we saw him—send the blood to be tested for Widal's reaction and if we get a negative result and there is still no evident disease to account for the pyrexia send another sample of blood? When I was called in to my first three cases of plague and I had a history of four apparently healthy individuals of the same household struck down within a day of each other with a disease characterised by fever I had no difficulty in pronouncing the disease infectious. As soon as I left that infected house I called on the medical man in attendance and he readily assented to my proposal that it was better for our patients, better for the neighbours and community at large, and better for our own professional reputations, to notify the sanitary authorities at once, although neither of us could give the disease a name. I notified them as probably ill-defined or doubtful cases of enteric fever requiring complete isolation and close observation for developments.

Respiratory symptoms.—On a physical examination of my patients I found in one nothing definite beyond congestive catarrh at the bases of both lungs. This was the natural sequence of cardiac failure, for the first sound of the heart was indistinct and he was extremely prostrate. He died on the third day after my examination. In another case there was a little bronchial catarrh and in the other two cases the chest was normal. The pneumonic form of plague is not only the most fatal form but the most difficult to diagnose, for "pain, tenderness, and enlargement of the lymphatic glands in the inguinal, femoral, axillary, and cervical regions, which are the most prominent external signs of bubonic plague, are absent." This is also the most infectious form, for the sputum is teeming with plague bacilli. One of the earliest and most striking symptoms is the dyspnœa which is out of all proportion to any physical signs revealed on examination. There is great pain in the chest and this, unlike the chest pain of acute pneumonia, is not localised but general and occasionally referred to the abdomen. There are cough and expectoration, but the sputum, while generally scanty and streaked with bright red blood, has not the glairy, viscid, rusty character of the sputum of acute lobar pneumonia. Rhonchi and râles can be heard but dulness and tubular breathing are seldom present. The characteristic pulse-respiration ratio of acute pneumonia is absent, although there are hurried breathing and quick pulse. Now in enteric fever we only find in the early stage a slight degree of bronchitis or bronchial catarrh. If pneumonia sets in it is a complication in a later stage when the disease has become typical. It is also in this stage that we find basal catarrh due to hypostatic congestion of the lungs.

Nervous symptoms.—In the case of the patient who died the nervous symptoms were a marked feature from the onset. He had "raved" all the previous night before I saw him. He was so restless that he could not be kept in bed, so he was allowed to get up, when he staggered aimlessly from place to place about the room [illegible] most of the time. When I saw [illegible] apathetic, and could answer [illegible] semi-comatose condition and very prostrate. Taking the case by itself with the mottling of the skin, as described in the Belvidere report, and no buboes being pointed out to him no man could distinguish it from a case of typhus fever. Another of my cases had a history of "raving" at the onset, while in the other two cases there were no pronounced nervous symptoms. The first case would be classed under the typhus form of plague, where the delirium, nervous prostration, muscular weakness, stupor, and coma are leading features of the disease. In enteric fever the nervous symptoms come on late in the disease, as a rule, when there is seldom any doubt in the diagnosis.

Diarrhœa.—In all febrile conditions the bowels are irregular and we find either constipation or diarrhœa. In two of my cases there was diarrhœa at the onset and in one of them it continued up till death. In the third case the bowels were normal and in the fourth case they were not noted at the onset. In the Glasgow cases diarrhœa was often present at the onset. It is stated that the general rule in plague is constipation unless in the intestinal form, when diarrhœa is present at the onset, and later blood, mucus, and epithelium appear in the stools. In regard to the appearance of the stools I was misled by a statement which was volunteered by a neighbour without any suggestion of mine. She said that the motions were like "pea-brae" (the word "brae" is the Scotch equivalent for soup) and that they had "an awful smell." I am afraid that she either meant that the stools were watery or she had heard of "pea-soup stools" and was too anxious to assist me in my diagnosis. In regard to the degree of offensiveness of stools I would place little reliance on the statements of patients or their attendants unless the attendant is a trained nurse. Now, in regard to enteric fever I agree with Dr. F. F. Caiger that "the fact cannot be too strongly emphasised that diarrhœa is by no means a necessary attendant of enteric fever." I have always found constipation to be present in ill-defined cases of enteric fever and they were ill-defined because there was no diarrhœa. At any rate, diarrhœa in enteric fever does not usually appear till the second week of the fever and when it does appear there is little doubt of the diagnosis.

Tenderness or pain in the right iliac region.—This was the most misleading of the three symptoms that favoured the view of the first three cases being probably enteric fever. It was no use trying to elicit it in two of the patients, for the one was semi-comatose and the other was a child. But the third patient, the mother of the other two, on palpating in the cæcal region, said that it was painful. I had no reason to extend my palpation along the right groin and if I had done so I would have discovered a large painful bubo to which she had directed the other medical man's attention and which he had ordered to be poulticed. The pain which I elicited was probably due to indirect pressure on this bubo or to an inflammatory condition of the deep iliac glands. Ever since that day—and I shall always continue to do so even in a woman—on palpating for cæcal tenderness I never fail to run my hand along the right groin.

Skin eruptions.—I found no rash or mottling of the skin in any of my four patients. One of them is described on admission to the hospital and after, I presume, a bath, which was much needed, as having a faint purplish mottling which was most marked across the lower part of the abdomen, the arms, and the buttocks. It resembled the mottling of typhus fever. There is no true skin rash in plague. There may be occasionally petechiæ or mottling but no distinct rash. As for the rose spots in enteric fever they are usually absent in ill-defined cases, and if they do appear it is never before the end of the first week when the case has become more or less typical.

The tongue.—In all febrile conditions for any length of time we find a tongue coated with white or yellow fur. The appearance of the tongue of my patient who died was the same as that of all patients in a low vital or typhoid condition. His mother's tongue was simply a febrile tongue and the appearance of the tongues of the other patients presented nothing specially striking. The typical tongue in plague is one "early coated with a creamy white fur except the tips and edges which are clean and red, later it is dry, covered with a yellowish or whitish-brown fur, the tips and edges remaining red and irritable." The appearance of the tongue in enteric fever varies from the ordinary febrile tongue to one glazed and morbidly red. I am afraid that the tongue, unless in association with other symptoms and signs, is of little practical value for differentiating the two diseases.

General aspect of the patient.—The aspect of the patient who died conveyed to my mind that of one in a very low or typhoid condition. The aspect of his mother was that of one who is very anxious to have some painful symptom relieved. Her one appeal to [illegible] sistent vomiting. [illegible] the aspect of the [illegible] again anxiety to relieve the painful buboes in each of her groins. It is one thing to study the aspects of a patient whom one is called in to relieve and another thing to study the aspect of a group of patients with the same disease lying quietly in the ward of a hospital. The characteristic physiognomy common to all forms of plague is—"In the early stage the countenance portrays anxiety and distress, later resignation and apathy, the eyes are red and congested, and the speech broken and hesitating and pronounced in a thick and husky tone like that of a drunken man." To the plague specialist the aspect would no doubt be a valuable sign, but it would be of little practical value unless in association with other signs to a man trying to diagnose his first case of plague—a disease which he has read about but never seen.

DISTINGUISHING FEATURES.

Buboes.—In the pneumonic and septicæmic forms of plague buboes are only found post mortem. It is therefore a blessing that "as a rule the first outbreak of plague in a community is bubonic in type, whatever it may become afterwards." In my cases the mother, according to the Belvidere report, noticed a painful swelling in her right groin, the day after the onset of the disease. The same report states that buboes were detected in the axillæ of the patient who died, as well as enlargement of the deep cervical chain of glands. The little boy was found to have a large submental gland of about the size of a marble. His mother was certain that it was not there prior to his illness. This [illegible] axillæ, neck, and groin were palpable but not distinctly enlarged. The young woman when I saw her 18 days after the onset of her illness had very palpable painful buboes in each groin. They were noticed by herself on the third day of her illness and were thought by the medical man in attendance to be gonorrhœal. I have pointed out[1] two points of differentiation—(1) the temperature of 104°, and (2) the rare situation in woman for gonorrhœal buboes—between plague buboes and gonorrhœal buboes. The time of the appearance of the bubo varies. It may be the first sign of the disease but it commonly develops while the temperature is rising on the second or third day. Its appearance is rarely delayed till as late as the eighth day of the illness. Very often pain and tenderness are present before any enlargement of the gland can be made out but they are soon followed by a palpable tender swelling. In the commonest type there is a large mass of several enlarged glands blended together by the surrounding exudation, but it may be only one inflamed gland with little infiltration present in the cases most rapidly fatal. The most common glands affected are those in the groin. In almost half of the cases the inguinal or femoral glands, or both, are alone enlarged. The next common situation is the axilla and in order of frequency the cervical submaxillary and parotid glands. Enlargement of the supra-trochlear, iliac, and popliteal glands rarely occurs.

---

[1] THE LANCET, Oct. 6th, 1900, p. 1040

Widal's reaction —This is an absolute positive test and almost an absolute negative test of enteric fever. Of 206 cases of enteric fever the blood serum gave the reaction in 201, and in 103 cases which were not enteric fever the reaction only occurred in one case and that in a case of typhus fever. The reaction can be rarely obtained before the sixth or seventh day of the attack and in some cases it ceases to react before the expiration of three months from the onset of the disease, while it can often be obtained for two years or more after recovery, but usually in a less degree of completeness.

A CASE OF COMPLETE COARCTATION OF THE ARCH OF THE AORTA; NECROPSY.

By W. LEE DICKINSON, M.D. Cantab., F.R.C.P. Lond.,
ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL;

AND

W. J. FENTON, M.B. Cantab., M.R.C.P. Lond.,
CURATOR OF THE MUSEUM, ST. GEORGE'S HOSPITAL; ASSISTANT PHYSICIAN TO VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

A MAN, aged 29 years, delicate looking and somewhat ill-developed, was admitted into St. George's Hospital on March 30th under the care of Dr. H. D. Rolleston. The patient stated that he had had an attack of scarlet fever when he was a boy, but had never suffered from rheumatism or chorea. In February, 1898, he was laid up with a severe attack of influenza, since when he had suffered from pains in the chest and palpitation of the heart, and more recently from cough. In January, 1900, he had a second attack of influenza, after which his breath remained so short that he was quite disabled. While in the hospital his chief subjective symptoms were referable to the heart itself and to an engorged state of the lungs. The heart's action was tumultuous and forcible, the impulse was diffuse, and the dulness was greatly enlarged. On auscultation the chief abnormal signs were a faint systolic murmur over the whole præcordium, a ringing aortic second sound, and a diastolic murmur in the aortic area, traceable down the sternum and audible also in the back. Marked pulsation was observed in the subclavian arteries, in the neck, and in the temporals; and on one occasion Dr. T. R. Whipham, medical registrar, observed pulsation in the back, between the left scapula and the spine from the third to the seventh rib. The radial pulses were equal, large, locomotor and collapsing. With rest in bed and tonic treatment, including small doses of digitalis and strophanthus, considerable improvement took place; and on April 25th the man was sent to the convalescent hospital at Wimbledon, where he came under the care of Dr. Lee Dickinson. The improvement, however, was not long maintained; dropsy set in with persistent hæmoptysis, enormous enlargement of the liver, and a scanty, lithatic, and highly albuminous state of the urine. A full trial was now made of digitalis, but without the slightest restraining effect upon the progressive cardiac symptoms, and death occurred on June 1st.

Necropsy by Dr. W. J. Fenton.—At the post-mortem examination it was found that the aorta was at first moderately dilated, but at the origin of the innominate artery it became slightly contracted, the contraction increasing along the arch until, at the origin of the subclavian artery, the lumen barely admitted the terminal phalanx of the little finger. Immediately beyond this point the lumen of the aorta was suddenly diminished to the size of a goose-quill by a sharp ridge which corresponded to a groove on its under surface. Between this and the junction of the ductus arteriosus the aorta formed a globular dilatation of about the size of a small marble, and then became suddenly and completely obliterated, the appearance externally being as if a ligature were tied tightly round the vessel, and internally that of two hollow cones placed in contact at their apices. The walls of the first part of the aortic arch were thickened and showed a few patches of atheroma, and the point of obliteration was encircled by a ring of early degeneration. The rest of the thoracic and abdominal aorta was narrow and thin-walled, but otherwise healthy. The ductus arteriosus was completely obliterated and reduced to a fibrous cord half an inch long. At the apex of the cone-like upper extremity of the descending aorta was a shallow depression which just admitted the tip of a bristle and corresponded to the end of the duct. The aortic valve was incompetent to the water test, and was provided with two cusps only, an anterior and a posterior, which were stiff and thickened and devoid of lunulæ. The coronary arteries arose behind the anterior cusp. The innominate, left carotid, and subclavian arteries, together with the left vertebral, which arose directly from the arch between the left carotid and subclavian, were dilated and thickened.

It was not practicable to trace out the anastomotic circulation with any completeness, but this had evidently been carried out chiefly by the internal mammary and first four intercostal arteries, which were greatly enlarged, thickened, and tortuous.

The heart, together with the arch and five inches of the descending aorta, weighed 33 ounces. All the cavities were dilated and their walls hypertrophied, especially the left ventricle, where these changes were extreme. The mitral and tricuspid valves and the pulmonary artery and its valves offered nothing for comment. The foramen ovale was closed. There was a fibrous tag on the front of the heart and the pericardium over the right auricle was opaque and thickened. There were several apoplexies in the right lung, the liver was nutmegged, and the spleen and kidneys were cardiac.

Clinical remarks.—Coarctation of the aorta is sometimes entirely latent and may be compatible with an active life and even the attainment of extreme old age; but in the majority of cases, sooner or later, the labour of carrying on the anastomotic circulation proves too great for the heart, which undergoes hypertrophy and dilatation—often to an extreme degree. The average age at which death thus results is said to be 34 years. In a considerable minority of cases death comes by way of rupture of a saccular or dissecting aneurysm of some part of the aortic arch; and, apart from aneurysm, there appears to be a noteworthy liability to rupture of the aorta, and even of the heart itself.

As for clinical diagnosis, given a fair development of the anastomotic circulation, and a sufficiently methodical examination of the patient before the essential lesion has been masked by secondary cardiac changes, there is no reason beyond the rarity of the affection why the diagnosis should not be achieved. Pulsation in the arteries of the head and neck is probably constantly excessive, while in the abdominal aorta it must be absent or much diminished. The femoral pulse, when it exists, is retarded beyond the radial. Sometimes there has been observed obtrusive enlargement and pulsation of the intercostal, scapular, mammary, epigastric, and other more or less superficial arteries; but there appears to be no absolutely fixed rule as to which vessels shall dilate, and even with complete coarctation the anastomotic arrangements may escape observation. In a clinical lecture on a presumed case of coarctation of the aorta, published in the *Medical Times and Gazette* of Oct. 17th, 1857, the late Dr. Walshe speaks of "heaving, expansile, forcible pulsation at two spots near the inferior angles of the scapulæ, with all the qualities of aneurysmal impulse," but in reality due to a dilated and knotty condition of the intercostal arteries, and in part of their posterior perforating branches So strong, indeed was that impulse that the idea of aneurysm of the arch itself, extending backwards, suggested itself for a moment to his mind. Something of the kind in a minor degree was observed in our case.

The greater part of Dr. Walshe's lecture, which is a delightful example of the logical method of clinical investigation, is occupied with the discussion of a special murmur upon d to turn. This murmur, gene- passage of blood through a con- coarctation, was of slightly ng quality, and very high pitch. at the second right interspace, close to the sternum, and it was conveyed upwards on each side, downwards and backwards to both vertebral grooves, but more intensely to the right than the left, on a level especially of the spines of the scapulæ. Barié in an able and laborious monograph published in the *Revue de Médecine* for 1886 speaks of the murmur having its maximum intensity over the course of the descending aorta between the left scapula and the spine, at the level of the third and fourth upper dorsal vertebræ. But obviously such a murmur is not to be expected when the coarctation is complete, and in our case it was certainly absent.

With regard to treatment we will only remark upon the failure of digitalis in our case and upon the fact that the same thing has been observed before.

Pathological remarks.—From the scattered literature of the subject[1] comprising 105 cases, we gather that coarctation of the aorta is of great, and, in its complete form, of extreme rarity. Only some 14 cases of the latter have been recorded. The male sex is more liable than the female in the proportion of seven to two. The coarctation is invariably situated at or near the junction of the ductus arteriosus with the aorta; sometimes a little below, rarely above, and never more than a centimetre distant. The constriction is generally produced by a fold of the inner coats of the artery, the outer coat being continued over it; very rarely the aorta has been found reduced to a fibrous cord for the length of about a centimetre, Occasionally, as in our case, the the intervening portion of the ve dilated. When the obstruction is incomplete the lumen may vary in size from that of a small probe to that of the index finger; when complete, the appearances are usually similar to those described in our case. The constriction may be either sudden or gradual; in the latter case the narrowing begins with the transverse arch, increasing as the ductus is approached, or it may begin at the origin of the aorta. Most frequently, however, the vessel behind the stricture is dilated or aneurysmal. In proportion to the degree of obstruction in the aorta the anastomotic circulation becomes over-developed, and the vessels chiefly concerned are thickened, dilated, and tortuous. These are the subclavian, the internal and external mammaries, the superior and inferior epigastrics, the intercostals and scapulars.

A full and illustrated description of the anastomoses will be found in Craigie's paper. In this connexion it is worth noting the marked contrast between the thickness and dilatation of the first part of the aorta and the thinness and diminished calibre of that succeeding the obstruction, the difference being probably explained by the lessened tension in the descending aorta, together with the conversion of a pulsating into a continuous stream, a point of some importance as bearing upon the diminution or extinction of the femoral pulse in these cases.

The changes found in the heart usually consist in dilatation and hypertrophy of one or both ventricles or of all the cavities. As a rule, aortic valvular disease exists, for the most part due to slow inflammatory changes induced by the abnormal strain to which the valve is subjected, and it is probable that the great weight of the heart in our case, as also in many others recorded in the literature of the subject, is due to compensatory changes induced by aortic incompetence rather than the direct result of the coarctation. In the great majority of cases the ductus arteriosus is closed and presents the usual appearances Thickening or other evidence of inflammatory change in connexion with this structure is quite exceptional

A point of great importance as bearing upon the pathogeny of aortic coarctation is the frequent association with it of valvular and arterial anomalies as well as congenital malformations in other parts of the body. The frequency of this association is given as no less than 37 per cent, and is possibly greater. Twelve chief associated malformations have been hitherto recorded: (1) patent ductus arteriosus; (2) transposition of the heart; (3) two aortic cusps; (4) patency of the undefended space; (5) absence of musculi papillares in the left ventricle; (6) hare-lip and cleft palate; (7) hypospadias; (8) deformity of the lower extremities; (9) two anterior communicating branches in the circle of Willis; (10) innominate and left carotid arteries arising from a common trunk; (11) triple division of the aorta at its origin; and (12) left carotid and subclavian arteries arising from a common trunk. To these must be added the irregular origin of the vertebral artery in our case.

From a study of the various theories we incline to the view that aortic coarctation arises shortly after birth from a congenital vice of development affecting that part of the aorta which lies between the origin of the subclavian artery and the junction of the ductus arteriosus, forming the so-called isthmus aortæ. This throughout fœtal life is narrower, and its walls thinner, than the rest of the aorta and iary rôle, but develops rapidly to take its share in the systemic vents resulting in the malformation appears to be as follows. The early post-natal changes in the circulatory system, including closure of the ductus arteriosus, take place in the usual manner, the congenital tendency making itself felt shortly afterwards in non-development of the isthmus aortæ, which, by retaining its fœtal narrowness, results in the enlargement of an anastomotic circulation. In some few cases retrogressive contraction of the isthmus takes place, amounting, it may be, to complete obliteration.

As already mentioned, the ductus is generally closed and the absence of evidence of inflammatory change in its neighbourhood, which by extension to the aorta might have produced coarctation, or of any direct connexion between the obstruction and patency or otherwise of the duct, seems to support the view that they are for the most part independent processes. In the few cases in which the duct remains open it seems probable that a degree of narrowness of the isthmus has existed in fœtal life sufficient to prevent its early closure; non-development of the isthmus then keeps it permanently open until a collateral circulation is established when the causes of patency cease to obtain, but the time for involution having passed the duct contracts, but remains pervious.

A CASE OF SEPARATION OF THE EPIPHYSEAL HEAD OF THE FEMUR.

By J. JACKSON CLARKE, M.B. LOND., F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS AT THE NORTH-WEST LONDON HOSPITAL, AND AT THE CITY ORTHOPÆDIC HOSPITAL.

INTRA-CAPSULAR fracture of the neck of the femur in young persons appears usually to be of the nature of a separation of an epiphysis. One of my colleagues at the City Orthopædic Hospital, Mr. John Poland,[1] has recorded a case in every respect similar to that which I now describe.

The patient was a well-grown girl, aged 15 years, who presented no evidence of rickets or other affection of the bones. Five months ago she fell down in the street and experienced such pain as to cause her to faint, and on regaining consciousness she found that she could not stand. She was seen by Dr. Rees who rightly diagnosed a fracture and had the patient removed on an ambulance to a hospital. On arrival in the casualty department she was examined, but the severity of the lesion was not, apparently, made out, since she was not admitted into the hospital but was told to rest and to rub the affected part with liniment She did this for some time and then with some difficulty began to get about again. In February last the patient came to me at the City Orthopædic Hospital. She was very lame and she said that she felt much pain on taking a step with the right foot. On examination I found that the right limb was markedly everted. The right great trochanter was displaced upwards and approximated to the anterior superior spine. The limb was an inch shorter than its fellow, and the gluteal fold on the affected side was shortened and curved up at its outer end. These features are shown in Figs. 1 and 2. On the front of the right hip-joint there was a prominence which suggested an anterior dislocation of the head of the femur. Passive adduction of the affected limb was easily accomplished, but *abduction* and *flexion* were painful to the patient and were greatly limited in their range. There was no crepitus felt in carrying out these movements. A good radiograph was obtained which clearly showed a break in the neck of the femur. The outline of the shadow of the head and the upper part of the bone, traced from the radiograph, is shown in Fig. 3. I must confess that until I had studied the radiograph I was a little doubtful as to the exact nature of the lesion. Once the latter had been ascertained the proper course of treatment was clearly indicated: nothing but excision of the separated head of the femur could give the patient relief. Accordingly, I recommended her for admission and she was taken into the hospital under the care of Mr. John Poland whose permission I have to mention the further history of the case.

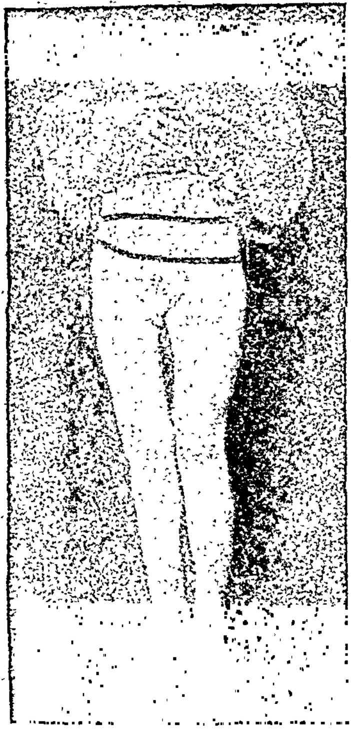
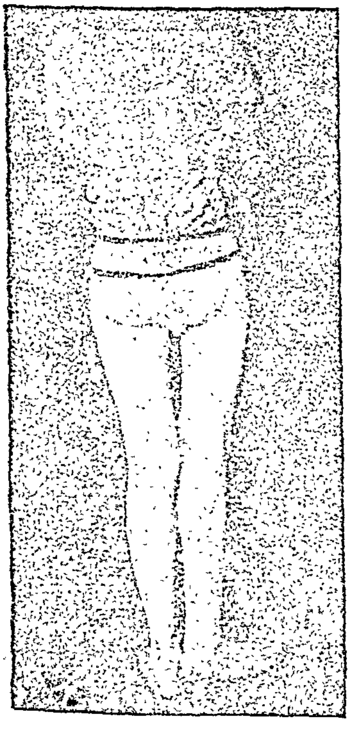
Fig. 1.



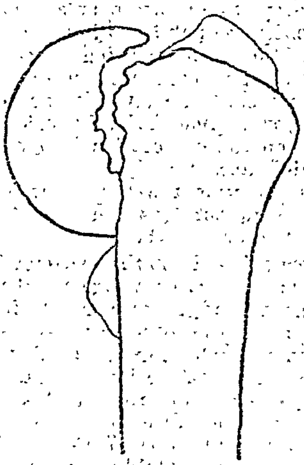
The appearance of the limbs seen from the front. The black tapes are placed respectively just below the anterior superior spines and just above the trochanters, and serve to show the elevation of the trochanter on the right side.

Fig. 2.



The limbs seen from behind; the gluteal fold curves upwards on the right side.

Fig. 3.



Outline of the shadow of the parts at the upper end of the femur traced from the radiograph and reduced to ½ scale.

At the operation the patient was anæsthetised by Mr. Henry Davis. It was observed that under anæsthesia there was some crepitus when the limb was moved. Mr. Poland, assisted by Mr. Chisholm Williams and myself, opened the joint from the front, the dissection passing externally to the rectus and iliacus muscles which were drawn inwards exposing the capsule of the joint. The capsule was then incised parallel with, and internal to, the ilio-femoral band. The fractured surface of the neck of the bone, thickened by an irregular formation of callus, was then seen, the head of the bone being entirely out of view and out of reach. (See Fig. 4.) Mr. Poland removed much of the callus, which was readily detached, and finally sawed

Fig. 4.

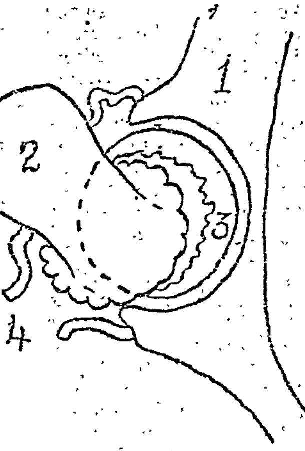


Diagram to show the relation of the fragments as in horizontal section: 1. Os innominatum with the acetabulum. 2. Neck of the femur with callus. 3. Head of the femur displaced backwards. 4. The anterior incision in the front of the capsule.

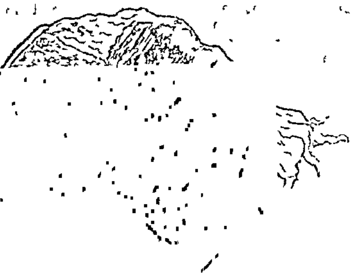
off the prominent inner end of the neck. The fractured surface of the head of the femur was now seen and it was levered out with an osteotome, the ligamentum teres being ruptured in the process. The wound was then closed throughout save where a small drain of iodoform gauze moistened with a 1 in 20 solution of carbolic acid was laid in from the acetabulum to the middle of the suture-line. The parts removed consisted of the head of the femur (which was entire), the inner end of the neck, and separate fragments of granular callus. The head had remained [illegible] the neck by two portions of the cervical [illegible] at its [illegible] [illegible] and another [illegible] teres also [illegible] [illegible] necrosis, but there was no attempt at bony union, the callus having been formed entirely from the neck of the femur. The separation had taken place exactly in the plane of the epiphyseal cartilage, no trace of which remained. (See Fig. 5.) The fragment of the neck which was removed was somewhat sclerosed.

FIG. 5.



Vertical frontal section of the head of the femur after its removal. The sawn surface of the anterior fragment is drawn its natural size.

The absence of crepitus until the patient was anæsthetised and the existence of a certain amount of ligamentous connexion between the fragments may account for the severity of the case not having been recognised by the young men who were first responsible for its treatment. The assistance of the x rays in the diagnosis of the case was very real. The deformity present in this case recalled what is seen in some cases of coxa vara, and coxa vara may sometimes arise suddenly owing to a green stick fracture of the neck of the femur in a rachitic subject. Although the patient in the present case had no definite signs of rickets there probably [illegible] of the bone from slight [illegible] in the juxta-epiphyseal [illegible] the accident. I may add [illegible] ly successful.

Old Cavendish street, W.

NOTES ON

CASES OF INJURY BY LIGHTNING: ONE FATAL.

By PHILIP EDWARD HILL, V.D., M.R.C.S. ENG., L.S.A.,

BRIGADE SURGEON-LIEUTENANT COLONEL SOUTH WALES VOLUNTEER INFANTRY BRIGADE.

ON July 27th, 1900, when acting as senior medical officer of Bulford Camp, Salisbury Plain, a terrific thunderstorm passed over the camp whereby one man was killed and 14 others were simultaneously prostrated by a single flash of lightning.

The fatal flash occurred at 1.15 P.M. I was at the time sitting at lunch close to the pole of the mess-tent, when my plate suddenly appeared to be filled with the electric fluid. I mechanically dropped my knife and fork, and as I did so an orderly hurriedly informed me that a private belonging to the 1st V.B. South Wales Borderers had been killed by lightning and that he had been removed to the regimental hospital tent to which I at once proceeded. Upon entering the tent I was impressed with the strong sulphurous smell that pervaded it. I found the patient lying on his back quite unconscious. His respiration was slow, deep, and interrupted, the pulse was slow and soft, the pupils were dilated, and the general appearance was that of an apoplectic seizure. *Stimulants were administered and every effort was* made by Surgeon-Lieutenant [illegible] [illegible] myself to [illegible] [illegible], but the [illegible] [illegible] the body after death cadaveric rigidity [illegible] been asserted that rigor mortis does not occur in persons killed by lightning, but this case does not substantiate the fact.) The only appearances that presented themselves were slight scorchings on the right thigh and buttock. No post-mortem examination was made. At the inquest, which was held on the following day, I gave the cause of death as nervous shock and heart failure.

The stocks of several of the rifles in the deceased's tent were shattered and split by the electric fluid passing down them, but there were no marks of burning, only slight fusion of the metal in some of them.

The following are the notes by Lieutenant H. Hardy, R.A.M.C., of the nature of the injuries which were received by the men who were admitted to the stationary hospital:—

1. Private, 1st V.B. South Wales Borderers. There were numbness and coldness of both legs, and slight marking on the right leg.

2. Private, 3rd Gloucestershire Regiment. There were slight marking and scorching of the left leg.

3. Private, 4th Gloucestershire Regiment. There was scorching of the left hand and foot, with deafness.

4. Private, 3rd [illegible] [illegible] the patient was unable to move [illegible] There were scorching and [illegible]

5. Private, 3rd Gloucestershire Regiment. The patient was unable to move the right leg below the knee and he was marked and scorched down the left side and arm. His clothes and boots were torn.

6. Private, 3rd Gloucestershire Regiment. Both legs and the left arm were scorched. The right arm was scorched slightly.

7. Private, 3rd Gloucestershire Regiment. There were loss of movement and numbness in the left arm.

8. Private, 3rd Gloucestershire Regiment. The left foot was painful. There was marking on the buttock.

9. Private, 3rd Gloucestershire Regiment. Both legs and the right hand were scorched and numbed and there was scorching over the abdomen.

10. Corporal, 3rd Gloucestershire Regiment. The face and leg were scorched.

11. Private [illegible] There were numbness in [illegible] left breast.

12. Private [illegible] The patient's left leg and left hand and his first, second, and third fingers were numbed.

13. Private, 1st Royal Welsh Fusiliers. There was numbness of the leg but no markings were present.

14. Private, 1st V.B. South Wales Borderers. There were tingling and numbness in both legs.

In many of the cases the effect upon the nervous system was very marked. Several of the sufferers were very restless and moaned piteously and so impressed were they with the dread of impending death that great difficulty was experienced in assuring them that they would recover.

Crickhowell.

HEALTH OF GLOUCESTERSHIRE.—*The report of* the medical officer of health and sanitary committee of the Gloucestershire County Council for 1899 shows that 8802 births were registered (2363 in urban and 6439 in rural districts), giving a birth-rate of 23 6 per 1000 (against 29 3 for England and Wales) 5458 deaths occurred (1568 urban and 3890 rural), equal to 14 97 per 1000, as against 18 3 per 1000 for England and Wales 1081 cases of scarlet fever were notified with 18 deaths; 361 cases of diphtheria, with 61 deaths; 163 cases of typhoid fever, with 34 deaths; and 21 cases of puerperal fever, with 12 deaths. Only one case of small pox was notified and the report adds that "the Vaccination Act is working successfully, the domiciliary visits and the use of sterilised calf-lymph seem to have disarmed the opposition of objectors and the neglect of the indifferent"

WEST LONDON HOSPITAL.

A CASE OF GANGRENOUS FEMORAL HERNIA; ENTEROSTOMY; SUBSEQUENT ANASTOMOSIS BY HALSTED'S METHOD AND OCCLUSION OF THE GUT.

(Under the care of Mr. LEONARD A. BIDWELL.)

THE decision as to the treatment to be accorded to the intestine in gangrene after strangulation must rest finally on the general condition of the patient. The ultimate advantages of an immediate resection are so great and so obvious that this operation should be performed whenever the patient's general condition will admit of it. Before gangrene of the bowel in a hernia can occur the obstruction must have been somewhat prolonged and the patient will in all probability have been reduced by the vomiting to a condition almost of collapse. In such a subject any operation must be badly borne and therefore any operative procedure should be as rapid and as simple as possible. The resection of the affected portion of bowel, however skilfully and rapidly performed, may easily prove too much for the already exhausted patient and he may succumb though he might have survived the formation of a temporary artificial anus. There are, however, cases in which the depression already existing is less and in these the surgeon is justified in endeavouring to save his patient the inconvenience of an artificial anus and the danger of subsequent operations by the performance of an immediate resection. No strict rule can be laid down. Some patients will be so exhausted as to be unable to survive any operation however slight; others will have strength sufficient to permit the formation of an artificial anus but nothing more; while in other cases an immediate resection will prove successful. For the notes of the case we are indebted to Mr. H. G. Woodhill, house surgeon.

A married woman, aged 60 years, was admitted into the West London Hospital on June 4th, 1900. Six days before admission a left femoral hernia had come down and since that time the patient had passed neither fæces nor flatus; stercoraceous vomiting had occurred during the last two days. Taxis had been freely employed without any effect. On admission the pulse was rapid and the tongue was dry and furred. In the left femoral region there was a large swelling, the skin over which was tender, red, and œdematous. The patient was immediately given chloroform and under the direction of Mr. Bidwell, Mr. Woodhill made a vertical incision over the swelling and exposed the sac; this was opened and a quantity of offensive blood-stained fluid was evacuated. The contents of the sac were found to consist of a mass of gangrenous omentum and a knuckle of gut which was also quite gangrenous. The omentum was first ligatured as high up as possible and cut away. A fine silk suture was then run round the margin of the lower part of the sac so as to diminish its size, the redundant part of the sac was cut away, and the remainder was sutured to the lower part of the knuckle of intestine. Gimbernat's ligament was divided and an incision was made into the gangrenous gut; and as practically no fæces came away a small rubber drainage tube was passed into the intestine under Poupart's ligament; through this a great quantity of fluid fæces escaped. The patient recovered well from the operation and rapidly improved in her general condition, but as the whole of the motions were passed through the artificial anus a considerable amount of irritation was set up round the wound, and the patient, after much persuasion, consented to have a further operation performed.

On July 27th Mr. Bidwell opened the abdomen by an incision in the mid-line below the umbilicus; the dilated portions of ileum going to, and the contracted portion coming from, the hernial sac were isolated. These two portions were then held together, and a lateral anastomosis was performed between them by Halsted's method at a point about two inches from the femoral ring. All the sutures having been passed openings about two and a half inches long were made into each portion of bowel, and the mucous membranes were united with a few points of suture. The anterior row of sero-muscular sutures were then tied, completing the anastomosis. The abdomen was closed, each layer of the abdominal tissues being sutured separately. The patient made a very good recovery and the amount of fæcal matter escaping from the artificial anus diminished. During the following four weeks attempts were made to stop the fæcal discharge by strapping and pressure, but as they were not successful Mr. Bidwell determined completely to exclude the artificial anus from the alimentary canal.

On August 13th the abdomen was reopened by a vertical incision in the left linea semilunaris and the two portions of intestine between the anastomosis and the artificial anus were clamped close to the anastomosis with rubber drainage tubing, and close to the artificial anus with clamp forceps, both pieces of gut were divided between the clamps, and the two ends, immediately below the anastomosis, were closed by a continuous suture for the mucous membranes and by interrupted quill sutures for the serous and muscular coats. A pair of dressing forceps was then introduced into the artificial anus and passed up the canal inside the gut till its ends were seen inside the abdomen; the free ends of the gut were then seized with these forceps and dragged down the canal and were fixed with a suture in the groin. (See figure.) The peritoneum round the internal femoral ring was then drawn together with a purse-string suture; in this way the femoral canal and its contained knuckle of gut were shut off from the peritoneal cavity. The abdominal wound was then closed by sutures layer by layer. About the fifth day after this operation a slough consisting of the excluded portion of ileum came away from the wound, which then quickly healed. The patient made a complete recovery and left the hospital on Sept. 5th.

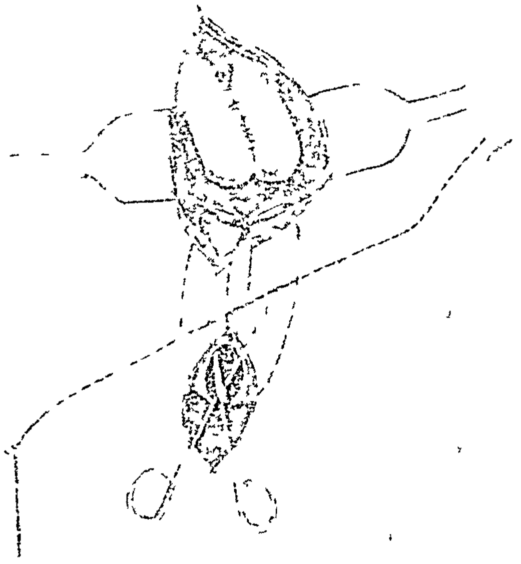

Diagram showing the lateral anastomoses and the method of drawing down the excluded knuckle of gut.

Remarks by Mr. BIDWELL.—The treatment of this case raises the question of the propriety of immediate resection of gangrenous intestine as advocated by Kendal Franks and others. The coil of intestine was firmly adherent to the walls of the sac, and so it would have been impossible to pull down healthy gut into the wound in order to perform an end-to-end anastomosis; moreover, the sac was full of fœtid contents and would have certainly infected the general peritoneal cavity had any communication existed. The method which I advised—namely, the formation of a temporary artificial anus—involved far less risk. It is noticeable that no fæcal contents escaped until a drainage tube was passed inside the gut through the femoral canal, so this procedure should be employed. When the patient had recovered from the operation the question of performing an end-to end or a lateral anastomosis presented itself. I decided in favour of the latter procedure, as it could be done with the least risk of fouling the peritoneal cavity, and I believe that a lateral is a much safer procedure than an end-to-end anastomosis, especially if done by Halsted's method; in fact, I have never seen any fæcal extravasation or peritonitis to follow this method when I have employed it. The operation of occlusion of the two ends of the gut going to the fæcal fistula completed the cure I have had to do this in another case of lateral anastomosis, also with a successful result.

With regard to the immediate resection of gangrenous gut followed by end-to-end anastomosis I have employed the method in two cases of femoral hernia both of which ended fatally. These, however, were cases of exceptional severity since in one case general peritonitis existed from rupture of the intestine above the stricture, and in the other the patient was practically moribund when placed on the table I am therefore strongly inclined to recommend the formation of an artificial anus in cases of gangrenous hernia, with subsequent treatment of the fæcal fistula by a lateral anastomosis.

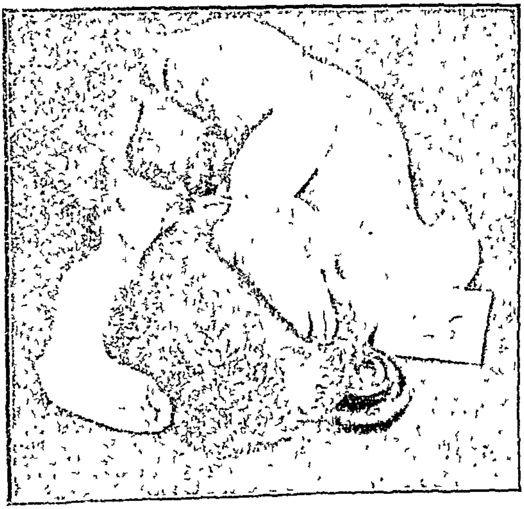
LIVERPOOL WORKHOUSE HOSPITAL.

A CASE OF PRESENTATION OF THE HEAD, CORD, AND FOOT; CONTRACTED PELVIS; CÆSAREAN SECTION; RECOVERY.

(Under the care of Dr. W. ALEXANDER.)

THE value of Cæsarean section is well shown in the following case. The mortality resulting from this operation has been found to vary greatly under different circumstances. The early figures compiled by Dr. Thomas Radford[1] gave 84 per cent of maternal deaths. Since that time the record has much improved, so that comparatively late statistics give mortalities varying from 40 to 25 per cent or even less. The much higher mortality after this operation which formerly obtained in towns as compared with country practice no longer exists, as it was due to septic complications which are now easily avoided. It is interesting to remember that at the end of the last century an "École Anti-Cæsarienne de Paris" endeavoured to get the operation declared illegal[2] For the notes of the case we are indebted to Dr. Henry Peet, resident medical officer.

A married woman, aged 25 years, was admitted into the lying-in wards of the Liverpool Workhouse Hospital on the afternoon of May 22nd, 1900. She had been in labour for three days and was beginning to show signs of exhaustion On examination the os was found to be fully dilated, the membranes had ruptured, and the liquor amnii had all drained away. The head was presenting with one foot beside it and the cord was prolapsed and pulseless. The bony pelvis was contracted in all diameters and the vagina also was very dry and contracted, so much so that it was impossible to introduce two fingers without great force and much pain to the patient. The pains were feeble and the patient was much exhausted and was crying out for delivery. Her previous history was as follows. She had been married two years and nine months She had had a miscarriage four months after marriage There had been no other confinement.



Showing the presentation.

Chloroform was administered and a short attempt at turning the child was made As this was found to be impossible it was decided to perform Cæsarean section at once, as some efforts at artificial delivery had been already tried outside. The operation was commenced as soon as the instruments could be got ready The usual preparations for an abdominal section were made The bladder and the rectum had previously been emptied An incision five and a half inches long was made, commencing above at the umbilicus and extending down the middle line to within two inches of the pubes. The incision was carried down to the peritoneum, the bleeding points being secured with compression forceps The peritoneum was opened and the incision was completed with scissors. The uterus was then pressed up out of the incision by an assistant, the uterine wall was opened in a line with the skin incision, and the child was seized by the knee and quickly extracted and given to an assistant. It was found to be dead, evidently for some time, and weighed eight and three-quarter pounds. The uterus was then pressed out of the abdominal wound by the assistant and the hæmorrhage was more or less controlled by firm pressure at its sides and neck. A subcutaneous injection of ergotin acted immediately and most effectually. The placenta, membranes, and clots were removed from the uterus, the uterine cavity was washed with a 1 in 1000 lotion of perchloride of mercury, and the walls were firmly pressed together, sponges being placed round the abdominal wound. Eight deep sutures of strong catgut were rapidly passed into the gaping uterine
bout half an inch from the edge
lecidual surface. These were
edges being tucked in The
hæmorrhage whic
severe then practi
was completed by
opposed peritone
neal surface of the uterus were then well washed with warm water. The parietal peritoneum was sutured with fine catgut and the abdominal wound was closed by eight perforating sutures of silkworm gut entering deeply into the muscular tissue. The whole operation occupied about 25 minutes.

The patient passed a fairly good night after the operation For the next fortnight the temperature varied between normal and 100° and 101° F. This was owing to the formation of a stitch abscess which necessitated the removal of three stitches and slightly re-opening and fomenting the wound. In other respects the patient made an uninterrupted recovery and was discharged from the hospital on Sept. 13th. The accompanying illustration shows the presentation of the child

---

WATER-SUPPLY OF KINGSBRIDGE.—At the meeting of the Kingsbridge (Devon) Urban District Council held on Oct. 16th it was decided to adopt a scheme for supplying the town with water from Capton Moor, Woodleigh, at an estimated cost of £10,000.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Wind Exposure and Phthisis.

A MEETING of this society was held on Oct. 23rd, Dr. F. W. PAVY, the President, being in the chair.

Dr. W. GORDON (Exeter) read a paper on Wind Exposure and Phthisis. He remarked that in view of the near prospect of the erection of sanatoria for phthisis in various parts of this country it might not be thought inopportune to discuss a subject which bore upon their choice of localities. The data upon which his paper was based were elicited when he was studying the distribution of the phthisis death-rate in Devonshire. After describing the methods which he had adopted he proceeded to consider the relation of the phthisis death-rate to the general death-rate, taking the latter as a guide to general conditions of sanitation. So far as could be judged the distribution of the phthisis death-rate in the rural sanitary districts of Devon was due to some other cause than that of general sanitation. The relation of the phthisis death-rate to the rainfall was next discussed, and it was shown that Tavistock with the highest death-rate had the most rain and Axminster with the lowest had the least rain; but other considerations went to show that instead of the rainfall causing phthisis the two must have a common cause, and this was probably the wind which brought the rain. Turning to the geology, it seemed evident that the soil alone would not account for the variation in the phthisis death-rate. As regards the relation of phthisis death-rate to wind Dr. Haviland had drawn attention to the fact that exposure to prevailing winds produced increase in phthisis mortality. Dr. Gordon next inquired into the degree of exposure of the different districts and found that Tavistock, which was more exposed to the west and south-west than any other district, showed the maximum phthisis mortality. The investigation of other districts led him to believe that on the whole it might probably be concluded that exposure to the west and south-west winds increased the mortality of phthisis. Dividing the different parishes of Devon into groups he found that the group of parishes where the dwellings were well sheltered from west and south-west winds had an annual phthisis death-rate of 0 24 per 1000. Parishes where dwellings were imperfectly sheltered from these winds presented an annual death-rate of 0 57 per 1000. Parishes where the dwellings were fully exposed to west or south-west winds or to both showed a death-rate of 1 34 per 1000. With regard to smaller areas, in Newton Abbot district the death-rate from phthisis in exposed parishes was more than half as much again as in sheltered parishes and imperfectly sheltered ones showed an intermediate mortality. Whatever influence was exerted by the soil it was subordinate to the influence of wind exposure. He did not think the difference in temperature, sunshine, or purity of air could account for the differences in phthisis death-rate, but unfortunately there were no means of scientifically measuring them. The conclusion at which he arrived was that certainly for the districts of St Thomas's, Newton Abbot, Okehampton, and Barnstaple, and probably for Devonshire generally, the paramount influence which determined a higher or lower rate of phthisis mortality was the degree of exposure to, or shelter from, the west and south-west winds. The paper was illustrated by maps tinted diagrammatically.

Dr. WILLIAM CAYLEY remarked that he did not think they would be justified in concluding that the prevalence of south-west or any other violent winds was the sole cause of the higher death-rate in certain districts. Wider investigation would be necessary. Some years ago when visiting the Scilly Islands he was struck by the number of deaths from phthisis. The climate of these islands was very mild, but the winds were very violent He noticed that the windows of the houses were very small and he suggested that the prevalence of phthisis was due to the inhabitants shutting themselves in at night and excluding all fresh air.

Surgeon-Major A G. BLACK thought it would have been interesting if Dr. Gordon could have given the duration of some of the cases—e g, were they longer in the north-west winds and shorter in the south-west winds? These winds undoubtedly introduced other causes which might themselves be the reasons of alterations in the death-rate noticed.

Dr. G. B. LONGSTAFF remarked on the laborious nature of such an investigation, but it should be remembered that they had to consider not only the conditions of the country around but the conditions of the dwellings of these people and their occupations. These circumstances had a very considerable influence on the phthisis death-rate, and without knowing these conditions they would not be justified in drawing conclusions as to the influence of winds and exposure as a cause of death. Lace-making was a very potent cause of the disease, and in some villages all the female population was so employed. Then there were the copper and tin mines at Tavistock. The question of the permeability of the soil was probably overshadowed by the immediate surroundings of a house or farmstead. The Devonshire people were notoriously dirty, especially in the way they kept their farmyards. The distribution of rainfall was an important factor, and differences of race ought to be considered. The question of diagnosis was also an important one when dealing with small figures, and especially when extending over a short period of time, as in this paper. He would have liked to have seen the tables from which the conclusions were drawn. They could then have seen the actual number of deaths on which the percentages were based. Another fallacy was the removal of cases to workhouses and other institutions; these sometimes affected the death-rate in a certain district in a very remarkable fashion. Was there any reason why the south-west winds should produce a higher phthisis death-rate? It might be by inducing "chills" or it might be that people shut themselves up at night in close bedrooms so as to exclude a violent wind.

Sir R. DOUGLAS POWELL thought that Dr. Gordon's investigations appeared to show that the death-rate was influenced by strong winds, but there were other factors than the prevailing wind which rendered a district unsuitable for phthisis. Dr. Haviland had shown some years ago that in the windy parts of England phthisis was more prevalent. It was not a question of the quarter from which the wind blew but the strength of the wind which was important. Moreover, he thought that this cause acted probably because it led the inhabitants to shut themselves up. He was very glad to have heard Dr. Longstaff's remarks, in which he concurred. It would be interesting to have similar observations from other parts of the country like those which Dr. Gordon had prepared.

Sir HERMANN WEBER remarked that the question of the influence of high winds on consumption was important, not only climatologically, but therapeutically. For purposes of sanatoria such observations were valuable. The "windiness" of a district rendered it unsuitable for a sanatorium. In his belief strong winds of any kind or from any quarter were injurious to consumption and increased the phthisis mortality; but the causes of phthisis were very numerous and it was very difficult to take one factor and examine that alone.

Mr. J. O R. BRAINE-HARTNELL remarked that exposure to high winds was, in his belief, the most important condition in phthisis, far more important than rainfall. At Nordrach and other sanatoria there were abundant woods and other shelter all around where patients could walk. They were not allowed to expose themselves to high wind. He would like to know whether the south-west wind was more injurious than the north-east wind.

Dr. P. H. PYE-SMITH wished to recognise the labour of such investigations, but he thought it was difficult to get sufficient numbers of cases for the [illegible] statistics. People ought not to speak of percentages until there were at least 100 cases Small areas constituted another source of fallacy, but this could probably be remedied on account of the widespread nature of phthisis. There were, he remarked, two sets of causal factors, one which led to the development of pulmonary tuberculosis, and another which hastened death after the patient had contracted the disease, and a different set of causes might be in operation for each of these.

Dr. W. P. HERRINGHAM remarked that three sets of observations could be made about a disease. One set of observations related to an individual case; another set consisted of observations on a series of cases; and a third set were those which related to the hygiene and surroundings of the cases. It was certainly advantageous for a person who knew the district well to make an inquiry such as this.

Sir WILLIAM BROADBENT questioned whether the facts revealed really connected the south-west wind with consumption It was always difficult in diseases when the causes were so complex as those of consumption to differentiate a

single factor.
prejudicial, th
patients
shutting themselves up at night. In his belief it was the strength of the wind and not its direction which was detrimental.

Dr. GORDON, in reply, said that he did not wish to state that the south-west wind was detrimental in all parts of the world, but it certainly seemed to increase the phthisis death-rate in Devonshire. He thought it was quite possible that the evils of wind might be partly due to shutting up at night. He doubted whether occupation much affected his statistics. He believed that the chief reasons why the south-west and west winds were bad was because they were the most prevalent, the most violent, and the wettest winds in Devonshire, to which, of course, all his remarks were confined.

MEDICAL SOCIETY OF LONDON.

Some Remarkable Cases of Sarcoma.—The Occurrence of Arthritis in Association with Appendicitis.

A MEETING of this society was held on Oct. 22nd, Mr. JOHN H. MORGAN, the President, being in the chair.

Mr. A. MARMADUKE SHEILD read a paper on Some Remarkable Cases of Sarcoma revealing some of the sources of error which attend the diagnosis of that disease. The
is issue.—Mr.
had published
of these was a
n the trachea
subsequently
disappeared entirely, although microscopical examination had shown it to be undoubted sarcoma. The patient remained healthy for six months and
Removal was attempted
tumour again subsided,
necropsy confirmed the sarcomatous nature of the growth, though at the time of death it had undergone considerable involution. The second case was one of multiple melanotic growths at the back of the neck which were removed, and although the patient remained under observation for some three years or more the growth never recurred. He was surprised to find what a number of cases—35 or more at the time he investigated the subject some years ago—were on record of undoubted sarcoma which had entirely disappeared. He referred to the great difficulty which might be experienced in the diagnosis between abscess and sarcoma and mentioned a case in point of alveolar sarcoma of the spine which had had all the features of abscess.—Surgeon-Major A. G. BLACK referred to a case of abscess of the breast which had been mistaken for sarcoma and also another case which was diagnosed as abscess which proved to be an encysted hæmatocele.—Dr. H. D. ROLLESTON referred to the capricious behaviour
Though
usually ver
the skin
were slow i
es which
he had seen in St. George's Hospital where melanotic growths remained local for some time and then spread slowly by the lymphatics. Some of the cutaneous melanotic cases were carcinomatous rather than sarcomatous.—Dr. CAMPBELL POPE referred to a case which he had seen some years ago of a man who presented all the symptoms of phthisis and subsequently abscess of the mediastinum. He one day brought up from the mouth a quantity of material which turned out to be of sarcomatous nature. This patient pursued an occupation which involved the inhalation of a good deal of dust.—Mr. H. F. WATERHOUSE referred to the case of a girl, aged 19 years, who went to the Charing-cross Hospital after an accident which resulted in fracture of the right humerus. The arm was put up in splints, but the bone was ununited at the end of four weeks. At the end of eight weeks, as there was still no union, an operation was performed and sarcoma was found to be deposited in the bone-ends. Amputation at the shoulder-joint was then performed. She had no return for eight years; then pleurisy developed on the opposite side which turned out to be of a sarcomatous nature and she shortly afterwards died from sarcoma of the left lung. He commented upon the length of time between the primary and secondary growths.—The PRESIDENT remarked on the advantages of reporting such cases. Nothing was more interesting than the growth and variety of sarcoma and it often caused much difficulty in diagnosis. The presence
was a most interesting point in Mr. Sheild's first case, for this was very unusual in sarcoma, though he remembered the case of a little boy in which this had occurred in the os calcis. He also referred to a case very closely resembling Mr. Sheild's second case, which commenced as an ulceration of the big toe, followed
of
the glands in the groin. He
of
always giving patients with tu
as
a matter of routine.—Mr. SHI
ief
object had been to illustrate the difficulties of diagnosis rather than rarity in his cases. Of all situations tumours of the breast were, perhaps, most likely to lead to mistakes. He thought that the giving of iodide of potassium should never be allowed to impair patients' chances of recovery by operation. He would have liked to have heard remarks on the occurrence of a rise of temperature in cases of sarcoma. It was not generally known that this occurred, and it was specially liable to give rise to errors in diagnosis, because there was a daily rise and the chart exactly resembled one of suppuration. He would also have liked to hear the views of other surgeons on the occurrence of thrombosis in these cases.

Dr. F. J. POYNTON read a paper on the Occurrence of Arthritis in Association with Appendicitis. He commenced by stating that the association of arthritis and appendicitis, though not common, was of interest because it seemed likely to throw light upon the etiology of perityphlitis. Some observers had suggested that rheumatic fever was an important cause of appendicitis and based that opinion upon (1) the associative occurrence of perityphlitis with acute rheumatism; (2)
resembling that of acute r
shortly after, an attack of
able reaction of some cases of perityphlitis to treatment by salicylates; and (4) the similarity in structure of the tonsil and vermiform appendix which it was suggested implied a similarity in pathological tendencies. Dr. G. A. Sutherland, in the Edinburgh Hospital Reports for 1895, published examples of this association occurring in children. Dr. Poynton brought forward a somewhat similar

a fortnight after which a sharp attack of perityphlitis commenced. Rapid improvement was followed by a relapse and a fresh outbreak of arthritis. Complete recovery ensued without operation under salicylates. The pyrexia was high and very irregular. As to the value of the treatment of perityphlitis by salicylates many explanations were offered. Dr. A. Haig considered it to be an evidence of the gouty origin, others of a rheumatic orig
Beverley Robinson had been
rheumatism and perityphlit
might be justly inferred fror
the success obtained by the treatment with salicylates was no proof of the rheumatic nature of the symptoms. Dr. Poynton thought that the evidence in support of the rheumatic origin of perityphlitis was not conclusive as yet. He had while registrar at St. Mary's Hospital investigated 60 cases of perityphlitis with the idea of gaining some more information upon the clinical side of the question. As his guide he had taken the manifestations of the rheumatic state as laid down by Dr. Cheadle in the Harveian Lectures for 1888. Every type of case was represented in this series, and in 31 the diagnosis had been verified by operation. In 11 there was a history of family or personal rheumatism, but in none of the cases could any causal relation between the two diseases be traced. In two of these cases there was polyarthritis. A good deal of light seemed to be thrown upon these difficult cases of polyarthritis by the papers of Plard
with appendiciti
experimental pro-
y injections of pure
papers had emphasised the point that metastases were especially liable to occur when the local lesion in the right iliac fossa was not well marked. Akerman had shown that intravenous inoculations of the bacillus coli into young rabbits would produce

osteomyelitis and also effusions into the neighbouring joints. These effusions were clear, turbid, or purulent, according to the local virulence of the process. Many observers had laid stress upon the importance of the bacillus coli in appendicitis and these organisms had been demonstrated in the metastatic abscesses. Dr. Poynton thought it was not surprising that the polyarthritis which sometimes complicated appendicitis should in the face of these observations closely resemble a rheumatic arthritis. The joint affections were multiple, might disappear during life, and might, as he had seen, react to treatment by the use of salicylates. Yet if death resulted a gangrenous appendix and visceral abscesses might be found, pointing indubitably to the metastatic origin of the arthritis. The severity of the joint lesions was probably dependent upon a local virulence at those sites. Death or recovery was probably dependent upon the virulence of the general poisoning. It seemed most probable that this polyarthritis was usually of the nature of a pyæmic rather than of a rheumatic lesion, and if this was the case it was an indication for immediate operation. Finally, allusion was made to cases of monarticular rheumatism of the right hip-joint in children, which for a while might closely simulate perityphlitis. The diagnosis was usually an easy one, for other rheumatic manifestations soon appeared in such cases as these, and the position was then clear. The active surgical measures that were now adopted for perityphlitis made the diagnosis of some importance. In conclusion, he was inclined to think that clinical evidence was, on the whole, against the explanation that appendicitis with polyarthritis was rheumatic, but upon this point he was anxious to obtain the opinions of the fellows of the society.—The PRESIDENT remarked that he thought that Dr. Poynton's view that the arthritis was of pyæmic and not of rheumatic origin was a correct one. He had seen cases which supported this opinion.—Dr H. D. ROLLESTON had hoped that Dr. Poynton would advance bacteriological evidence in support of the rheumatic origin of appendicitis. Dr. J. Cavafy had long been in the habit of treating appendicitis with salicylates. He (Dr. Rolleston) thought that the structural analogy between the tonsil and the appendix supported the view that appendicitis might be of rheumatic origin. There seemed to be a prejudice against this view founded on the idea that operation might in consequence be neglected. He suggested that the initial stage of appendicitis might be rheumatic but the other forms of infection might be added later and introduce a septic element. Some cases of appendicitis certainly recovered under salicylates. He could not remember to have seen appendicitis during rheumatic fever, nor had he seen definite joint mischief in the course of appendicitis.—Mr. F. C. WALLIS expressed the opinion that arthritis might be due not only to appendicitis but to other lesions of the bowel as well. He had seen and recorded cases of ulceration of the lower bowel associated with painful condition of the joints accompanied by swelling and effusion which were entirely relieved by removing the portions of the diseased bowel. He thought that a good many of the unexplained joint cases might be due to septic matter absorbed from some ulcerating surface. He was inclined to question the rheumatic nature of appendicitis —Dr. T. D. SAVILL mentioned the case of a man, aged 30 years, who had suffered from prolonged arthritis of many joints which would not yield to salicylates or other remedies. The patient died from perforated appendix and there seemed every reason to believe that the chronic joint mischief was of a pyæmic nature secondary to septic absorption from the appendix. He could not subscribe to the rheumatic origin of appendicitis.—Dr. H. A. CALEY referred to the scarcity of arthritic or other rheumatic manifestations in association with appendicitis, which he regarded as a strong argument against the existence of an intimate relationship between rheumatism and appendicitis. There seemed, however, to be a distinct bearing upon some cases of catarrhal colitis and rheumatic symptoms, and in this way—through the medium of the colitis—the rheumatic state might at times be concerned in the etiology of appendicitis.—Surgeon-Major A. G BLACK thought that a connexion might be traced when an abscess round the appendix became absorbed into the femoral sheath.—Dr. POYNTON, in reply, said that he had no wish to dogmatise. Certainly Dr. G. A. Sutherland's cases were very instructive. The children were undoubtedly rheumatic and they had had appendicitis. The occurrence of arthritis in appendicitis was probably rare but this might be accounted for in the present day by the prompt surgical measures which were adopted. As regards Mr. Wallis's question, he could not say whether any of the cases he referred to had had colitis or not.

HARVEIAN SOCIETY OF LONDON.

The Advisability of Early Operation in Cases of Acute Inflammation of the Appendix.

A MEETING of this society was held on Oct. 18th, Dr. W. H. LAMB, the President, being in the chair.

Mr. C. W. MANSELL MOULLIN read a paper urging the Advisability of Early Operation in cases of Acute Inflammation of the Appendix. After giving a brief account of the pathology of inflammation of the appendix, showing that it always originated from invasion of the mucous membrane by septic organisms from the interior of the bowel, he divided the cases, so far as surgical treatment was concerned, into three main groups. The first, by far the largest, included all those mild attacks which subsided of themselves or under the simplest treatment. In these the organisms were destroyed or removed before they could do any permanent harm; the lymph, which had been poured out, disappeared again without leaving any adhesions, and the appendix regained its normal shape, size, and mobility. These cases needed no surgical treatment. In the second group were comprised all those cases in which the absorption of the exudation was incomplete. In some it became organised; in others it broke down into pus; in others, again, a concretion was left behind. But all agreed in this one particular—that perfect recovery did not take place and was impossible without operation. Finally, there was the third group, fortunately by far the smallest, in which acute septic peritonitis broke out and in which the only possible chance of recovery was immediate operation. In all acute attacks it was absolutely essential to group the case in one of these three divisions within 36 hours of the onset of the symptoms or it might be too late. It was known that the interior of the appendix was full of septic organisms; it was known that if the conditions were favourable to them they could penetrate the wall with ease and infect everything; and it was known that the appendix was hanging free in the peritoneal cavity. The danger was not in performing a simple exploratory operation but in delaying to do so. All that was necessary was an incision one and a half inches long and the introduction of the finger in order to ascertain exactly the condition of the appendix and the peritoneum around it. Mr. Mansell Moullin then discussed the symptoms by which the cases which would recover of themselves might be distinguished from those in which operation would be required, sooner or later, either because of diffuse septic peritonitis or because of the formation of adhesions, strictures, or concretions. The pulse was the most valuable of all. If the pulse rate at the end of 36 hours while the patient was lying in bed was over 100 in the minute, or if in the course of the last few hours it had increased much in frequency, there was no doubt that the attack was a severe one and that operation would be required. The temperature was no certain guide unless it continued to rise. The intensity of the pain was of great significance, and so were also, but perhaps in less degree, local tenderness, muscular resistance, and a sense of fulness in the right iliac fossa. Vomiting, constipation, and the other symptoms usually present could not be relied upon in the same measure. Mr. Mansell Moullin laid great stress upon the fact that the absence of any individual symptom was of no account and that operation should be performed in any case in which the pulse was very rapid, even if the other symptoms did not point to any great degree of severity. If morphia had been given this rule should be even more stringent. The limit of 36 hours, he admitted, was a perfectly arbitrary one. All could not wait so long. Some could wait longer without undue risk. Each case must be judged upon its merits and this must be regarded merely as an average. The point to bear in mind was that at the beginning of a severe attack they could not as yet distinguish cases which might be allowed to wait from those which might not; that they would all of them have to be operated upon at last, some for adhesions, some for abscesses, and some for concretions or other causes (for severe cases did not recover without leaving some complication behind) and that it was wiser that a simple and practically safe operation should be performed at once upon all alike than that the disease should be allowed to run its course, and that those in whom diffuse septic [illegible] allowed to die in ord[illegible]n which they would [illegible] adopting the genera[illegible]ossible danger ahead [illegible] the condition of things [illegible] it was wiser to see how matters stood, provided it could be done without undue risk, than to trust to chance. But a preventive operation of this kind must be clearly distinguished from what were commonly called early operations—those performed upon the fourth or fifth days, which nearly always were too late and simply served to bring surgery into discredit.

Mr. RAYMOND JOHNSON was glad that Mr. Moullin had insisted upon the importance of a rapid pulse as an indication that an attack of appendicitis was a severe one. He entirely agreed with this view and had often noticed the serious importance of increasing rapidity of the pulse-rate in many acute abdominal conditions even when the other symptoms seemed to be favourable. He advocated early operation in the sense in which the term had been used by Mr. Moullin. He did not believe that in a case of acute appendicitis in which the inflammation was from the first localised by adhesions the risk of subsequent peritoneal infection was considerable. If performed early the operation would undoubtedly be done in a considerable number of cases in which a satisfactory result would have followed without it, but here and there it would save a life which would otherwise be lost. The practice could only be justified if in itself the operation involved no serious risk to life. It was strongly felt that the danger of the operation was very small indeed and that the risk of subsequent trouble from bulging of the scar was largely preventable if division of the muscular layers of the abdominal wall was avoided, the muscle fibres being merely separated. Mr. Johnson would hardly have anticipated that altogether reliable evidence as to the condition of the appendix could have been obtained by the introduction of the finger through the very small opening used by Mr. Moullin, and he would have feared the risk of disturbing the adhesions around a small collection of pus. For these reasons it was thought that a more free exploratory incision was advisable.

Dr. F. W. COCK, Dr. S. H. BELFRAGE, and Dr. E. CAUTLEY also took part in the discussion.

OPHTHALMOLOGICAL SOCIETY.

Cases of Blindness from Gunshot Injury of the Orbit.—Orthoptic Treatment of Convergent Squint in Young Children.—Cysticercus of the Eye.—Exhibition of Cases.

AN ordinary meeting of this society was held on Oct 18th, Mr. G. ANDERSON CRITCHETT, the President, being in the chair.

Mr. E NETTLESHIP read a paper on Blindness from Bullet-wound of the Orbit in which he gave details of six cases in which the sight of one eye, or sometimes of both eyes, was lost or injured by the passage of a bullet through the orbit without wounding the eyeball. These had been written of as "indirect [illegible] of the eye" in which the passage [illegible] part of the orbit was followed [illegible]ing into the vitreous, and as this cleared up by various and mixed appearances of choroidal rupture, choroido-retinal exudation, and changes at the disc without shrinking of the eyeball or any sign that the globe had been ruptured. The question as to how these injuries were produced was answered by the description of a case in which the eye was excised by Cohn and examined by Waldeyer in 1871. Cohn concluded that a contusion which directly affected only the outer surface of the sclerotic might set up severe and extensive plastic inflammation in the subjacent retina and vitreous. Mr. Nettleship mentioned other cases by Cohn, as well as one shown before the society last year by Dr. F. Menteith Ogilvie. He then described his cases in detail. The feature of interest in them was the extensive damage of the choroid and retina without wound of the eyeball. These indirect injuries were to be explained by the force of the projectile being changed into radiating vibrations of the tissue particles, acting as Professor W. F. Stevenson of Netley says—"as secondary missiles." These, passing through the dense sclerotic without damaging it, seriously injure the less resisting choroid and retina, whilst the bullet dragging on the muscular insertions might also contribute towards the injury. Mr. Nettleship mentioned some interesting experiments by Cohn and Stevenson, which had also been verified by himself, in which they had fired bullets at cylindrical metal vessels, some containing air only and others water, in both cases with no lid on the top. He showed photographs and the actual cylinders from his own experiments. In the former cases the bullet went through without producing much effect on the surrounding parts, but in the latter, which contained water, the vibrations set up in the fluid had produced very marked changes around the holes the bullets made. In this way the spinal cord might be injured by vibrations passing through the bone without fracturing it. He then compared the results of bullet-wounds with those of optico-ciliary neurotomy and also with the experimental evidence produced by Poncet, who in healthy rabbits cut the optic nerves and the posterior ciliary nerves. This latter caused from the eighth day onwards degeneration of the nerve elements of the retina, with increase of its fibrous structures, marked papillitis, and some inflammation on the outer surface of the vitreous; later the choroid, near the disc, became atrophied, and finally the degenerated retina became pigmented In all these cases there was a great tendency for the retina and choroid to become united by inflammation, and this explained the slight tendency there was to detachment. In most of these gunshot cases other cranial nerves were involved and the commonest paralytic sign was ptosis.—Other cases were mentioned by Mr. DONALD GUNN, Mr. G. HARTRIDGE, Dr. R. GRUBER, Mr. TREACHER COLLINS (who had had two), Dr. S. JOHNSON TAYLOR, and the PRESIDENT.

Mr. C. WORTH described the Orthoptic Treatment of Convergent Squint in Young Children and said that he commonly commenced treatment as follows The refraction was corrected and glasses were worn constantly. In nearly 30 per cent. of constant monolateral squint this treatment sufficed to render the eyes "straight," and in some of them binocular vision was obtained and the case was cured. In the 70 per cent. which were not cured by glasses operative treatment was postponed until the age of from seven to eight years, but only a small proportion of these obtained binocular vision, the time having gone by when this might have been developed. There were three chief difficulties to be overcome in carrying out orthoptic treatment in young children: (1) the child would only submit to treatment so long as he found it interesting; (2) the suppression of the vision of the squinting eye; and (3) the angle of the squint was usually so great that an ordinary stereoscope could not be used even if there were no suppression. This difficulty was overcome by an instrument invented by Mr. Worth by which the stereoscope could be adapted to suit a squint of any angle or direction and so stereoscopic vision was possible (The instrument was shown and carefully described.) He found that those who saw binocularly naturally arranged themselves into three distinct classes according to the degree in which they possessed this faculty, thus—first grade, simultaneous macular perception; second grade, true fusion with some amplitude; and third grade, sense of perspective. Mr. Worth then described the treatment, but before commencing it the visual acuity of the child's squinting eye was obtained The instrument was then adapted to suit the angle and direction of the squint and a cage, for instance, was shown before the fixing eye and a bird before the squinting eye The child then saw only the cage with the fixing eye The illumination of this was gradually diminished while that of the bird was increased until the bird was seen Should the cage then have disappeared the illumination was modified until the bird was seen in the cage. Many other devices were used until the child learned to blend the two images, and so they got Grade I. After a time the angle of the instrument might be altered slightly without destroying the picture; the eyes followed the object and maintained fusion, and so Grade II. was produced. Exercises were then continued until the third grade of binocular vision was produced. Next, the illumination of the object slides was gradually equalised and then an attempt was made to separate the mirrors more and more while the visual axes followed the deviation of the objects. Mr. Worth had found that this treatment in some hundreds of cases caused a disappearance of the squint and the acquisition of the highest grade of binocular vision. In other cases, though patients had Grade III. while looking into the instrument, the squint did not disappear. An occasional visit with exercises was sufficient to preserve the fusion faculty until the child had arrived at an appropriate age for operation. The desire for fusion then overcame any slight defect which might remain and a perfect cure resulted. The special points of this instrument were: (1) its adaptability to any form or degree of squint, including those cases in which the globe was rotated about an antero-posterior axis; (2) suppression of vision of squinting eyes was gradually overcome by unequal illumination; and (3) the variety of devices shown in the instrument interested and amused the child, so that he would readily give all the help he could at a most important point.

Mr. Nettleship related a case of Cysticercus in the Eye which had come under the care of Dr. David Wood of Cape Town. The patient was a cook first seen by Dr. Wood on April 6th, 1900, after spending some time on the Modder River. On dilating the pupil he saw some choroidal changes and on the outer side a large round greyish body. On May 2nd he saw the living cysticercus moving its suckers and the crown of hooklets was also visible; the vision was failing. In June the vision was worse and by July 15th it amounted to light perception only, and this was due to the fact that the retina was becoming detached. The cyst was then loose in the eyeball, but no details of the head were visible. On arrival in England in August Mr. Nettleship saw the patient. There was then a large cyst seen at the upper part of the vitreous covered with fine white calcareous bodies. A dense white patch was seen in one part which frequently gave a heaving movement. On Sept. 7th movements were still visible. The eye being blind the question of operation was not entertained. The patient had now gone back to South Africa and this was the last note up to the present time. The man had first noticed some affection of the eye in November last.—Mr. W. Lang expressed surprise that in the early stage, when it was (he thought) sub-retinal, no operation was undertaken. He cited an instance in which successful extraction of a cysticercus from near the macula was performed by Alfred Graefe.—Mr. Nettleship, however, stated that he gathered from Dr. Wood's notes that it was in the vitreous when he first saw it.—Dr. D. Little said that he had seen five or six cases of cysticercus in the vitreous and in appearance they resembled that described by Dr. Wood. If left to themselves the eye became blinded by slow but progressive choroido-retinitis. In two he tried to extract the cyst, but this was not successful, and in both the eyes became worse and had to be excised a few months later. Some had been successfully removed, but his own experience led him to look upon the prognosis as extremely bad, no matter whether an operation were attempted or not.

The following cases were shown:—

Mr. H. Work Dodd: Voluntary Bilateral Nystagmus.

Mr. E. K. Campbell: Double Cataract after Typhoid Fever.

Mr. H. B. Grimsdale: Double Congenital Lacrymal Fistula.

Mr. W. Lang: Rupture of Nerve Fibres at the Optic Papilla.

Dr. F. W. Edridge-Green: A case of Trichromic Colour Blindness.

Mr. John Griffith: Symmetrical Exostoses in the Neighbourhood of the Lacrymal Sac.

Mr. Treacher Collins and Dr. J. S. Hinnell: Diminished Tension and the Appearance of Optic Neuritis persisting for nine months after a Wound of the Orbit from a shot from an Air-gun.

Mr. J. Herbert Fisher: Tubercle of the Conjunctiva.

Northumberland and Durham Medical Society.—The annual general meeting of this society was held in the library of the Royal Infirmary, Newcastle upon-Tyne, on Oct. 11th. The following officers were elected for the ensuing session:—President: Mr. J. Rutherford Morison. Vice-Presidents: Dr. W. Robinson, Mr. J. L. Crisp, Dr. J. W. Smith, and Mr. G. W. Ridley. Secretaries: Dr. Thomas Beattie and Mr. Albert M. Martin. Committee: Dr. R. S. Peart, Dr. J. Adamson, Dr. W. Gowans, Dr. J. Murphy, Dr. G. H. Hume, Dr. D. Drummond, Dr. James Drummond, Dr. James Limont, and Dr R. A. Bolam.—The first ordinary meeting of the session was then held, the newly elected President occupying the chair.—Mr. W. G. Richardson exhibited two cases aft [illegible] Suppurating Peritonitis resulting [illegible] both cases following a few hours aft [illegible] appendicitis there had been sudden abdominal pain with collapse, and though operated upon 30 hours later when in an apparently hopeless condition the patients had recovered. Pus in each instance was diffuse in the peritoneal cavity and treatment had consisted in a free incision sufficient to permit of evacuation and adequate drainage, and the avoidance of lavage and in its place careful [illegible] drainage being effected by strips of gauze placed in [illegible] hepatic pouch, &c.—The exhibition [illegible] a general discussion on appendi[illegible] evidences indicating operation, i[illegible] Davies, Dr. A. A. Martin (North Shields), Dr. G. R. Murray, Dr. Beattie, Dr. Robinson, Dr. Gray, Dr. R. Buttercase, and Mr. A. M. Martin took part.—The President, after reviewing the discussion, stated in answer to questions asked that, in his opinion, the most important points indicating operation were—(1) a second attack; (2) a lump; and (3) a sudden acute onset.—Mr. W. G. Richardson also exhibited a child after operation for Cerebellar Abscess. The child, aged seven years, had been operated upon one month previously for cerebellar abscess following suppurative otitis media. Recovery from such a condition was much rarer than its occurrence.—Dr. J. Gray read notes of a case of Phthisis cured in the Durham County Sanatorium, with brief notes of 14 other cases. The man, aged 22 years, had suffered from hæmoptysis, cough, and consolidation of the right apex. Tubercle bacilli had been plentifully demonstrated in the sputum. After ten days' treatment the cough and expectoration had disappeared. Four months later the patient was discharged; he was able to walk 15 miles and had gained a little over two stones in weight, but there were still slight physical signs. Dr. Gray then read a detailed table of 14 cases at various stages of phthisis, showing results of sanatorium treatment.—Dr. W. Robinson also brought forward a patient treated in the same sanatorium who had also gained over two stones in weight, was able to walk 20 miles in the day, was in apparently rude health, and without detectable physical signs. He remarked that cases of consolidation offered a better chance of ultimate recovery than cases of excavation.—The following members also took part in the discussion: Dr. T. Oliver, Dr. G. R. Murray, Dr. Beattie, Dr. I. G. Modlin, and Dr. Ethel Williams.—Dr. G. H. Hume showed a patient after Double Intestinal Resection and Anastomosis for Malignant Growth. This man, aged 48 years, had but slight symptoms of six months' duration and presented a firm, nodular mass in the epigastric and left hypochondriac region of the size of a fist. On laparotomy there were no evident glandular involvement and no secondary nodules. The mass involved primarily the transverse colon and was adherent to and infiltrated the mesentery of a coil of small intestine, necessitating the resection of about 12 inches of colon and a similar length of small intestine. The cut ends of colon were joined by direct suture, the small intestine being anastomosed laterally by a Murphy's button. The Murphy's button had been removed from the rectum three weeks after the operation. The specimen was also shown and seen to be a sloughing carcinoma of the transverse colon, remarkable for the scant symptoms it had given rise to.—Mr. A. M. Martin exhibited a rare example of Congenital Deformity. The child, 15 months old, was born after a normal labour and exhibited the following condition of hands and right foot. Three middle fingers of both hands were partially arrested in growth and webbed; the webs showed deficiencies at the bases. The index finger of the right hand had at the situation of the terminal inter-phalangeal joint a deep transverse furrow, and at the situation of the first inter-phalangeal joint an attempt at formation of a supernumerary finger. In the right foot the second and third digits were completely webbed and the fourth and fifth partially. There was a supernumerary toe at the end of the big toe.—Dr. Oliver exhibited two cases of Splenic Enlargement. The first was that of a man aged 34 years. He had been under observation for two years and gave a history of enteric fever and also gonorrhœa followed by stricture. He complained of pain, weight, and increasing abdominal swelling; he presented an enormously enlarged spleen extending down to the pelvis and to the right of the middle line. There were no hæmorrhages. The blood was characteristic, presenting evidences not only of anæmia but also of leucocytosis and myelocytosis. The second case was that of a man aged 36 years. He had been in the army abroad and

had suffered f

specimens were also exl
G. Turner: A series of 3 no-
logy of Appendicitis.—Dr. G. R. Murray: Pork with Cysticerci Cellulosæ with microscopic slide of same.—Dr. Hume: A large Hydronephrotic Kidney—Dr. Beattie: Aneurysm of the Pulmonary Artery in a Phthisical Cavity from which Fatal Hæmoptysis had occurred.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—The first meeting of the session of this society was held on Oct 16th.—Mr. W. H. Horrocks, the retiring President, introduced the President-elect, Mr. F. Farrow, who then took the chair.—After a vote of thanks to the retiring President Mr. Farrow delivered his inaugural address, "Some Suggestions on the Work of a Medical Society," and in the course of his remarks urged (1) that a greater number of members should contribute papers and show specimens, not necessarily waiting till they had a rare case or specimen to communicate; (2) that members engaged in various branches of scientific research should bring before the society not only their finished results but should demonstrate and give accounts of their methods; and (3) that each member who experienced pleasure or derived benefit from attendance at the meetings should induce his medical friends to join the society. The greater the roll of members the larger was the fund of experience on which the society could draw. Further than this, a large membership was desirable in that it developed the social aspect of the society, which was quite as important as the scientific aspect and was of great value in causing the medical men of a district to have mutual knowledge of, and confidence in, one another and thus promoting a spirit of friendliness and *esprit de corps*.—Dr. J. Kerr showed a number of Sketches of the Fundus Oculi from recent cases The cases included glaucoma, pigmentation of the macula, and blocking of the retinal vessels.—Mr. Basil Hall showed the following specimens: (1) Sloughing of an Ovarian Cyst due to Stretching of the Pedicle; (2) "Baker's Cyst" of the Elbow from a case of osteo-arthritis; and (3) Bones from a case of Amputation of Both Feet for Gangrene.—Dr. C. F. M. Althorp showed the following specimens: (1) Sarcoma of the Breast from a patient 60 years of age; and (2) Vermiform Appendix from a case of Recurrent Appendicitis; the appendix contained a large concretion and was adherent to the ovary and Fallopian tube.—Mr. J. R. McGee showed an Oxalate of Lime Calculus removed from the urethra of a child aged five years.—Dr. H. Angus showed a Gall-stone of about seven-eighths of an inch in diameter which had caused acute intestinal obstruction and had been passed by the rectum after the administration of enemata. It had been probably impacted in an annular growth of the sigmoid.—Dr. William Craig showed the kidneys from, and read notes of, a case of Uræmia caused
by extreme attenuation of the kidney The
total weight of the two ains.
The patient was a single aver
She fell in the street, afte , while
stooping to pick up a handkerchief, and struck her head on the ground. When seen a few minutes later she was lying in a dazed state and though able to give her name and address she could tell nothing more. She had worked regularly up to the time of seizure, but occasionally had to leave work on account of "sick headaches." There was no history of alcohol, syphilis, gout, rheumatism, lead poisoning, or scarlet fever. On admission to hospital her temperature was 98° F., and her pulse was 60, irregular, and not of high tension. There was no cyanosis or dropsy. The pupils were contracted and equal. The tongue was dry and furred. The heart's apex beat was in the nipple line; the second sound was reduplicated at the apex; there was no accentuation of the second sound. During the first night urine and fæces were passed involuntarily More than a pint of urine was drawn off during the following day; the specific gravity was 1012; albumin was present in abundance; there was no sugar and no blood; hyaline casts were seen on microscopic examination. She lay in bed in a dazed condition. There was frequent jerking of the limbs. No paralysis was detected. On the day following admission she recovered somewhat, was able to swallow, and could move all her limbs. There was retention of urine. The pupils were unequal, the right being dilated. On the following day she passed into a state of coma
death. On opening the

Dr Craig said that the
only be made after the necropsy, as before death cerebral compression from hæmorrhage or injury could not be excluded. Another point of interest was that the kidneys continued functionally active in spite of the extreme shrinkage of the secreting substance. The absence of cardiac hypertrophy and of vascular change was also surprising. Lastly, in the absence of the causes usually assigned to nephritis, it was difficult to see what was the exciting cause of the attack.—Dr. D. Goyder, Dr. W. Mitchell, Dr. H. J. Campbell, and Dr. J. Kerr discussed the case, and Dr. Craig replied.

IPSWICH CLINICAL SOCIETY.—A meeting of this society was held on Oct. 20th, Mr. C. K. Moseley being in the chair.—Mr. J. R Staddon showed a case of Congenital Dislocation of the Patella The left patella was dislocated outwards. The patient suffered no inconvenience, being able to walk, to ride a bicycle, &c., like a normal individual.—Mr. W. F. Fryer showed an oldish man with a large Papillomatous Growth rising from the skin of the back just above the left buttock.—Dr. H. H. Brown showed a specimen of a Ruptured Tubal Pregnancy. When first seen the patient was in a state of collapse, almost pulseless, and with a
distend nces of
saline s to be
full of and a
double ligature was applied. After rallying slightly the patient died on the following day. The specimen showed
al.—Dr. Brown
Carcinoma of
aper on Extra
Uterine Pregnancy with notes of two cases. Case I.—The patient was a multipara, aged 36 years There had been no distinct menstruation for four months; abdominal swelling had been noticed for one month. The swelling was central, rising almost to the umbilicus; it was dull on percussion with resonance on both sides. The swelling was slightly tender. The cervix was fixed forwards behind the pubes. The uterus could not be well defined, being surrounded by what was taken to be inflammatory thickening. A sound was passed in to the normal extent and showed the uterus to be strongly anteverted. Slight losses of blood per vaginam occurred and the temperature after a time began to rise. An incision through the posterior vaginal wall where pus was thought to be gave exit to a small quantity of foul grumous material. The temperature fell, but the general condition of the patient became worse Laparotomy revealed a large cyst behind

months pregnancy and three weeks previously of what was supposed to be a miscarriage Only one slight hæmorrhage per vaginam occurred 18 days after admission to hospital. She complained of pain in the upper part of the abdomen. A rounded swelling could be felt on the right side reaching to within an inch or two of the umbilicus and separate from the uterus. The uterus was fixed with the cervix jammed down into the vagina Attacks of acute pain in the swelling led to operation. This revealed a large thin-walled vascular cyst close to the right side of the uterus. It contained blood, placental
tissue, an s very profuse
and salin the operation.
The patie operation but
made an Hossack, Mr.

Reigate, Mr. J. R. Staddon, Dr. Fowler Ward, Mr. Fryer, and the President joined in the discussion which followed.—Mr. Wynne Davies showed (for Dr. R. K. Casley): 1. A case of Amputation at the Hip-joint by the Anterior Racket Method for a large Sarcoma of the Femur. The patient was a girl, aged 21 years. The growth was very rapid, involving the upper half of the femur and the vertical chain of glands in Scarpa's triangle. She made a good recovery and there was no sign of recurrence six weeks after operation. 2. A girl, aged 15 years, with an Intractable Intestinal Fistula the result of a typhlitic abscess two years ago. Three operations had been done with only temporary success. A fourth operation in which the bowel was thoroughly freed from all adhesions to the surrounding tissues, the sinus being cut out and a double row of Lembert sutures inserted, had resulted in a permanent cure.

Glasgow Southern Medical Society.—The annual dinner of the Glasgow Southern Medical Society was held on Oct. 18th in the St. Enoch Station Hotel, Glasgow. A large and representative gathering of medical gentlemen assembled under the chairmanship of Dr. William Watson, President of the society. Dr. John Stewart and Dr. William McMillan acted as croupiers. Sir Hector C. Cameron, Honorary President, was the guest of the evening, and among others present were Principal Story, Professor John Glaister, and Professor Ralph Stockman. At the close of a well-served repast the chairman proposed "The Queen and Royal Family" in felicitous terms.—To Dr. John Stewart was assigned the toast of "The Navy, Army, and Reserve Forces"—proposed in excellent words—and replied to by Surgeon Lieutenant-Colonel A. Napier.—Mr. R. H. Parry then gave the toast of "Our Honorary President," and in doing so made reference to the honours which had recently fallen on the shoulders of Sir Hector Cameron. From Her Majesty the Queen he had received the honour of knighthood, and by the University he had been selected for the chair of Clinical Surgery, and it seemed appropriate that at about the same time he should be elected to the position of honorary president of the Glasgow Southern Medical Society.—Sir Hector Cameron, in responding, thanked those present for the cordial manner in which they had received the toast. While he valued the honours of which lately he had been the recipient he could not but feel gratified by the knowledge that he was also receiving honour at the hands of his own professional friends. He could assure them that it would be a source of pleasure to him to be of service at any future date to the Glasgow Southern Medical Society.—Dr. E. Duncan proposed the toast of "The University" and emphasised the lamentable position of laboratory accommodation in the medical faculty.—Principal Story, in acknowledging, said that the present wants of the University resolved themselves into one of finance. He was glad to be able to inform them that already some of these wants had been supplied. For some time laboratory extensions had been in progress and he hoped that at an early date further extensions would be inaugurated. To this end money was required and he felt convinced that as soon as the wealthy men of Glasgow realised the present needs the necessary funds would be forthcoming.—The other toasts which followed included "Our Society," proposed from the chair; "Kindred Societies," proposed by Dr. D. MacGilvray and replied to by Professor Glaister and Dr. S. Sloan; "Our Guests," by Dr. J. W. Allan, acknowledged by the Rev. D. McCorquodale; and "The Chairman," by Dr. C. E. Robertson.

South-West London Medical Society.—A meeting of this society was held at Lavender-hill, S.W., on Oct. 10th. Dr. B. Duke occupied the chair in place of the President, Dr. M. G. Biggs, who was absent through illness.—Mr. Noble Smith, surgeon to the City Orthopædic Hospital, gave a demonstration on the use of apparatus in orthopædic surgery generally and for spinal curvatures in particular. He showed how advantageously the medical man could apply his surgical knowledge in the efficient construction and application of such apparatus so as to fix diseased joints very thoroughly. He considered that if such a course were generally adopted there would be far fewer severe operations required, operations which left the patient minus a joint or a limb. If tuberculous disease of the spine could be almost always cured by fixation and general treatment—as it could be—then there could be no reason why the same disease in other than spinal joints could not be treated with equally good results. It was chiefly a mechanical question, a question of efficient fixation. Mr. Noble Smith then demonstrated the application of a spinal splint made of malleable iron which could be adjusted and fitted by the surgeon himself with great accuracy. By use of this apparatus in angular curvature gradual and considerable straightening of the curvature and expansion of the thorax and freedom of respiratory movements were obtainable. It was in every respect more effective than the ordinary "jacket." In treating lateral curvature where an apparatus was necessary the use of the muscles was encouraged and not interfered with. A series of photographs was exhibited.—Mr. Noble Smith further showed some plaster casts portraying the stages of treatment of severe varus as carried out at the City Orthopædic Hospital. The ultimate result was very satisfactory, producing a natural foot freely moveable, without that rigidity which almost invariably followed severe operations on the bones.—Several members of the society who took part in the subsequent discussion expressed themselves as having been very favourably impressed by the results of the treatment of spinal deformities in cases which had come under their own observation.

Glasgow Pathological and Clinical Society.—The first meeting of the present session of this society was held on Oct. 8th, Mr. A. Ernest Maylard, Vice-President, being in the chair.—Dr. T. K. Dalziel showed: 1. A specimen of Epithelioma for which the horizontal portion of the right lower jaw had been removed. He aimed at avoiding hæmorrhage during, and cicatricial contraction after, the operation; with the former in view he cut gradually down from without, ligaturing the vessels as they were divided; to avoid cicatricial contraction he sutured the mucous membrane of the cheek to that of the floor of the mouth and obtained union by first intention. Six weeks later the displacement of the remaining half of the jaw was barely half an inch, while by a slight effort the patient could oppose his teeth perfectly. 2. Hypertrophied Mammæ which he had removed from a girl aged 15 years. The organs weighed respectively 7 lb. and 4½ lb.—Dr. T. S. Meighan showed a patient who had suffered from Diplopia due to traction inward of the eyeball by the cicatrix following the operative treatment of a pterygium. Dr. Meighan had dissected up the scar and slid into the space upper and lower flaps of conjunctiva, completely curing the deformity and the diplopia.—Dr. Alfred A. Young showed a specimen of a Myxoma from the scalp of a man, aged 38 years. The tumour was thought to be a wen till cut into at the operation. It was situated superficially to the aponeurosis and was firmly attached to the skin, part of which had been removed along with the tumour. Microscopically it presented some of the features of angeio-myxoma.—Dr. J. H. Teacher read a further note on Menstrual Decidua.—Dr. John Gordon showed a specimen in which the Gall-bladder Communicated with the Transverse Colon by a Tubular Canal, probably of the nature of an inflammatory adhesion.—Professor R. Muir showed a fresh specimen of an Appendix Perforated by Ulceration and containing a Concretion.

Foreign University Intelligence.—*Copenhagen:* Dr. Wanscher has been appointed Extraordinary Professor of Surgery.—*Florence:* Dr. Livio Herlitzka has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Genoa:* Dr. Carlo Tarchetti has been recognised as *privat-docent* of Medical Pathology.—Dr. Buccelli of Naples has been recognised as *privat-docent* of Neurology and Electro-therapeutics.—*Halle:* Dr. Karl Grunert, *privat-docent* of Otology, has been granted the title of Professor.—Dr. Tschermak of Leipsic has been recognised as *privat-docent* of Physiology.—*Helsingfors:* Dr. Tigerstedt of Stockholm has been appointed to the chair of Physiology.—*Kiel:* Dr. F. Klein, *privat-docent* of Physiology, has been granted the title of Professor.—*Modeno:* Dr. G. Palazzi has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Naples:* Dr. Alberto Solaro has been recognised as *privat-docent* of Medical Pathology, Dr. D. Ventra as *privat-docent* of Psychiatry, and Dr. Nicola Sorrentino as *privat-docent* of Dermatology and Syphilography.—*Prague* (*Bohemian University*): Dr. K. Kuffner has been appointed Professor of Neurology and Mental Diseases. (*German University*): Dr. Schloffer has been recognised as *privat-docent* of Surgery.—*Rio de Janeiro:* Dr. Antonio Bittencourt has been appointed Assistant Professor of Medical Physics and of Organic Chemistry.—*Tubingen:* Dr. Sarwey, *privat-docent* of Gynæcology, has been appointed Extraordinary Professor.—*Utrecht:* Dr. T. Ziehen of Jena has been appointed to the chair of Psychiatry.

Reviews and Notices of Books.

Optique Physiologique. Leçons professés à la Sorbonne par le Dr. TSCHERNING. (*Physiological Optics.* Lectures delivered at the Sorbonne by Dr. TSCHERNING.) Paris: Carré et Naud. 1898. Pp 335.

THE talented young author of this book, who is well known as a translator into French of the works of Dr. Thomas Young, has endeavoured to give to the student within the limits of a portable volume an intelligible account of physiological optics. The mathematics introduced into the text are not beyond the comprehension of a moderately well-instructed reader and are not more abstruse than those that are to be found in Donder's classical treatise on the Refraction of the Eye published by the New Sydenham Society. He divides the book into three parts, the first treating of Ocular Dioptrics; the second of the Functions of the Retina; and the third on the Movements of the Eye and Binocular Vision. The early chapters are devoted to the consideration of the ordinary laws of dioptrics and catoptrics with definitions of such terms as "point of fixation," "visual line," "optic axis," and the "angle *α*." A particularly good account is given of the images of Parkinje and the mode in which they can best be observed, no less than six images are described. A chapter is occupied with the principles of ophthalmometry, and Dr. Tscherning describes an ophthalmophakometer that he has devised to determine the angle *α*. He speaks warmly in praise of Dr. Young's optometer. Anomalies of refraction are considered at some length and their relief by glasses is explained. The subject of regular and irregular astigmia is particularly well treated and many illustrative drawings of the latter are given.

An interesting chapter is devoted to the consideration of the various theories that have been advanced from the time of Kepler to the present on the accommodation of the eye. Dr. Tscherning, it is now well known, has advanced a theory of his own to explain the phenomena of accommodation, but he remarks in a note on Helmholtz's theory that great men should really be very reserved in their statements for fear of misleading their followers and partisans. Helmholtz, for example, suggested that the cornea is an ellipsoid, and although he especially states that the cornea does not resemble such a surface, the idea has been so rooted in men's minds that it is difficult to eradicate it, and so with his theory of accommodation, as will be seen if the trouble is taken to compare the doubtful phrases which he uses with the positive statements contained in books professing to give his views. The participation of the posterior surface of the crystalline lens in accommodation, a principle that everyone regards as certain, was in Helmholtz's estimation only highly probable. Dr. Tscherning himself holds that accommodation is effected by the transient formation of an anterior lenticonus by muscular effort, and this he considers to be the result of traction exerted upon the periphery of the lens. The lens, he maintains, has a soft outer layer, to which he applies the term "accommodation layer." The defective capability of accommodation of the eye in advancing years is due to the reduction in thickness of this soft external layer. It has been erroneously held, he is of opinion, that traction exerted on the zonule effects the flattening of the surfaces of the lens and that compression exerted on the periphery of the lens augments its curvature. The exact opposite really obtains—namely, that compression exerted on the periphery of the lens flattens the surfaces, whilst traction effected on the zonule augments the convexity of the lens at its centre whilst flattening that body at its periphery. Dr. Tscherning's observations on the change of form of the lens and on the images of Purkinjé were ingeniously made on himself by the use of an ophthalmoscopic mirror. In considering the subject of ophthalmoscopy he demonstrates that the size of the image of the disc seen in the inverted image of the fundus of an emmetropic eye through a + 13 D. glass is enlarged about five times In speaking of skiascopy or retinoscopy he reconciles the different expressions used by Parent and Leroy to explain the nature and movements of the shadow in that mode of examining the eye.

The functions of the retina are briefly discussed under the several headings of the luminous, the chromatic, and the form senses The several theories of colour are dwelt upon at considerable length, leading him to remark that the subject of colour has not as yet found its Newton. The last part of the book is occupied with the movements of the eye and binocular vision. Enough has been said to indicate that these lectures should be read by every student of ophthalmology, and we venture to say that all who do so will derive pleasure and profit from their perusal.

Flesh Foods, with Methods for their Chemical, Microscopical, and Bacteriological Examination. By C. AINSWORTH MITCHELL, B.A. Oxon, F.I.C., F.C.S. London: Charles Griffin and Co., Limited. 1900. Pp. 336, Price 10*s.* 6*d.*

OUR knowledge of all that pertains to flesh foods is certainly very widely scattered and a *résumé* of the various contributions on the subject was needed. In the work before us Mr. Mitchell has undertaken this task in a thorough manner and with success The subjects involved are not easy to collate, especially as they embrace so many departments of specific knowledge. The author defines the work as a practical handbook for medical men, analysts, inspectors, and others. Physiology, bacteriology, and chemistry are all necessarily indicated in an inquiry into the nature and character of flesh foods. Again, the microscope is an essential aid in discriminating normal or abnormal flesh and in indicating the existence of parasites and in identifying them. Nor is a macroscopic examination without value, and, indeed, a close study of the appearance of meats enables the examiner to pass judgment on the fitness or unfitness of meat for human consumption. The importance of the book is accentuated when this particular bearing of the study of flesh foods is regarded. The work is exhaustive, as will be seen from the following broad synopsis of its contents. Chapter I. deals with the structure and chemical composition of muscular fibre, Chapter II. with the structure and composition of connective tissue and blood, Chapter III. with the flesh of different animals, Chapter IV with the examination of flesh, Chapter V. with the methods of examining animal fat, Chapter VI. with the preservation of flesh and the composition and examination of preserved flesh products, Chapter VII. with the composition and analysis of sausages, Chapter VIII. with the proteids of flesh, Chapter IX. with meat extracts and flesh peptones, Chapter X. with the cooking of flesh, Chapter XI. with poisonous flesh, Chapter XII. with the animal parasites of flesh, Chapter XIII. with the bacteriological examination of flesh, and Chapter XIV. with the extraction and separation of ptomaines. Of these chapters those relating to chemistry, composition and analysis are in our opinion the best written. The chapter on meat extracts and flesh peptones is specially valuable in usefully presenting in review the chemical methods in vogue for the valuation of meat extracts, peptones, &c. It must be confessed that the differentiation of the various digested products by chemical means is still far from satisfactory and, further, we have no definite idea as to the real physiological value of the various definite products which have been thus chemically separated. It is the fashion now to determine the total proteids by means of bromine water and the albumose by "salting out" with zinc sulphate, but who shall affirm that the physiological value of a given preparation varies directly with the amount of constitutents indicated by these precipitants? The chapter to which we have referred is, however, valuable, as we have said, because it recounts the methods of analysis employed by various observers in the separation of proteids and, moreover, gives the results obtained with several well-known meat preparations. To some extent, therefore, we are enabled to comprehend the various methods at a glance and to get some idea of their comparative worth or worthlessness in throwing a light upon the value of the preparations as real nutrients.

With the general plan of the book we have no fault to find; the subject is admittedly difficult of classification. A decided improvement in the arrangement of the subject-matter, however, would have been a greater display in type of the headings of the various chapters so as more sharply to distinguish the headings of the chapters from the headings of the paragraphs. In some cases the headings of the paragraphs are in larger capitals than the headings of the chapters. This is a disadvantageous arrangement when searching through the pages for the different subjects. We are aware of no work in the English language which is devoted entirely to "flesh foods," although the importance of having at hand all that has been usefully written upon the subject compactly between two covers is obvious. The possession of a copy of Mr. Mitchell's work will save medical men, analysts, sanitary inspectors, and others an infinite amount of reference which previously had to be made to a score of books each touching upon the subject only here and there.

The Origin and Character of the British People. By NOTTIDGE CHARLES MACNAMARA. London: Smith, Elder, and Co. 1900. Pp. 234. Illustrated. Price 6s.

WITHIN the last few months a veritable epidemic of works on ethnology, anthropology, sociology, and the allied sciences appears to have infected authors and publishers alike, and what with Keane's "Man, Past and Present," Deniker's "Races of Man," Ripley's "Races of Europe," and the recent translation of Haberlandt's "Ethnology," we must confess to a certain sense of bewilderment. As regards the volume under review, in that it deals with a subject of such personal interest as the evolution, moral and physical, of our own race, there can be no doubt that it will appeal to a large number of English readers for whom abstract works on ethnology would have fewer attractions. Starting with the primitive inhabitants of these islands, from the evidence of craniology and palæolithic research, we are presented with a very fair picture of the general physical and mental development of the race from which we originally sprang. The picture becomes still clearer when we come to the period of foreign immigration which set in in a westward direction and left its mark by intermarriage and association on the natural characteristics and qualities of a people who seemed almost incapable of independent mental evolution.

As far back as the time of the Roman invasion the Iberian or primitive stock was already mixed with a Mongolian and Aryan element, and before the time of William the Conqueror there had been a further fusion with Teutonic races. This free intermingling with the hardy Teutonic elements has endowed the British people with great vigour and pliability of character—virtues which were not conspicuous in our original Iberian progenitors. Contrasting the diverse elements which constitute our composite character it is not altogether reassuring to learn that there are indications of a re[illegible] to the Iberian type to be noticed among the other than good results. of efficient f[illegible] working classes of London and other large towns, and that this tendency is not c[illegible] alone but unfortunately [illegible]

The psychological similarities and differences which are peculiar to different races, the reasons for their manifestation, and the effect of their operation, constitute sociological problems which are suggestively and ably dealt with by the author in his concluding chapter. For instance, concerning the future settlement of South Africa, we are reminded that the Boers are derived from the same branch of the human family as we are ourselves, and that they possess distinctive racial characteristics—"a brave, self-reliant people, who under just laws and with strict regard to their prejudices and hereditary sentiments will in time fraternise with the Anglo-Saxon." But whether or no abstract sociology has general application in practical politics this advice with regard to our "brother Boer" has a practical and withal a familiar ring. In those portions of the book which have reference to the evolution of man we cannot help thinking that the author exhibits less breadth of view than when dealing with the more general questions of ethnology. While admitting that all evidence goes to prove that man and the anthropoid apes are descended from a common ancestor he maintains that the main factor which has determined their distinctive differences is to be discovered in the method of ossification to be observed in their respective skulls. The skull of man possesses greater "innate power of growth" and the frontal sutures remain longer open: the brain is in consequence allowed greater freedom of expansion than obtains in the case of the animals lower in the scale. A distinction of such fundamental importance can hardly be drawn with justice from the evidence of craniology alone. The problem is one of general biology which admits of no such simple solution. If it be true that the gorilla has been condemned to eternal brutality merely because the protective envelopes of his brain refused to expand and that man became man because the same structures spontaneously enlarged, there is less in the influence of environment and the response of protoplasm to external stimuli than many of us are inclined to believe.

Dealing, however, with a subject of wide human interest Mr. Macnamara has marshalled his facts and theories in a logical and scholarly spirit and has contributed a scientific and literary volume to the goodly library of works by medical authors.

Diseases of Women. By E. C. DUDLEY, A.M., M.D. Second edition, revised and enlarged. With 453 Illustrations, of which 47 are in Colours, and eight Full-Page Plates in Colours and Monochrome. London: Henry Kimpton. 1900. Pp. 717. Royal 8vo. Price 21s. net.

AS it is only two years since the first edition of this book was published the author has had merely to modify and re-arrange the work and make such changes and additions as were necessary to secure greater accuracy and completeness. One of the defects that we noticed when the book first appeared—viz., that no separate account was given of the functional disorders of menstruation and of sterility—has been remedied by the addition of another part to the book. This includes a detailed account of the disorders of menstruation and of sterility. The pathological states in which these symptoms are present are described and their appropriate treatment is pointed out. These chapters will no doubt increase the usefulness of the book to students and practitioners.

The sections upon diagnosis and cystitis have been largely added to. Dr. Dudley points out "that the management of cystitis has risen from the plane of empiricism and has taken its place upon the scientific basis of pathology." This change is due mainly to recent investigation (especially bacteriological) into its etiology and improved modes of examination and of treatment. Attention is drawn to the important fact that in a large number of cases the urine remains acid and that cystitis is only a symptom and not a distinct disease. The value of the endoscope and cystoscope is very great and by their use alone can a certain diagnosis be made and efficient treatment be carried out. Routine washing out of the bladder is condemned. In the chapter upon diagnosis an interesting account is given of "Harris's Segregator," an ingenious instrument for collecting the urine separately from each ureter. It consists of two catheters, their straight portion being inclosed in a flattened tube and each being separate and moveable upon its longitudinal axis. The instrument having been introduced into the bladder the catheters are rotated so that their curved bladder ends lie one on either side of the trigone. A metallic lever which can be attached to the catheters by a metal arm is introduced into the vagina and its upper end is elevated so as to raise that portion of the bladder wall which lies between the two separated ends of the rotated catheters, and so form a watershed. The urine as it escapes on either side from the ureters flows out through the catheter of the same side. The instrument is certainly ingenious in conception. It is claimed that it has advantages over the ureteral catheter in that it can be used by the non-expert, does not invade the ureters, and therefore cannot injure or infect them. The book retains its chief characters and we still think, as we remarked in our notice of the first edition, that it is of unequal merit and somewhat badly proportioned. It gives, however, a very interesting view of the practice and opinions of one of the prominent American gynæcologists. It is a pity that the author has been compelled to increase its size by some 78 pages. 31 new illustrations have been added and six very excellent coloured plates. At the present day the art of book-illustration has been carried to such a high pitch in America, and such beautiful examples of it have recently appeared in some of the American text-books, that it is a little disappointing to find how poorly many of the illustrations in this work are reproduced, especially such as are original. We can commend the work to those who wish to know something of the American school of gynæcology.

LIBRARY TABLE.

Ethnology. (Temple Encyclopædic Primer Series.) By Dr. MICHAEL HABERLANDT. Translated by J. H. LOEWE. London: J. M. Dent and Co. 1900 Pp. 167. Illustrated. Price 1s.—This little work on ethnology, one of the latest additions to the "Temple Primer" series, has been translated from the German of Dr. Michael Haberlandt by Mr. J. H. Loewe. Dr. Michael Haberlandt, although an accepted authority on the subject of ethnology, has not the gift of literary fluency, his style is ponderous even for a German. Unfortunately the translator has kept so closely to the idiomatic style of the original German that the reader is frequently forced to a mental paraphrase before he arrives at the meaning which certain sentences are intended to convey. The subject-matter, although necessarily condensed, is interesting and suggestive from start to finish and it affords the reader a very fair insight into what may be called the alphabet and grammar of the science Although ethnology is by no means confined to the prehistoric history—if we may use the paradox—of the races, so far as this little work is concerned the story of mankind mostly leaves off where written records and papyri take up the narrative. The contents are divided into three sections. The first deals with the forces in the life of nations which have contributed to their development; the second section is concerned with the culture of the different races; and the third and largest section gives a short statistical survey of the present distribution of nations and a systematic history of the more important races of man. The reader who has made himself acquainted with the contents of this unpretentious little volume will be sufficiently well versed in the moral, mental, and physical characteristics of man in all their ethnological manifestations to form a thoroughly reliable picture of mankind.

The Human Frame and the Laws of Health. (Temple Encyclopædic Primer Series.) By Dr. REBMANN and Dr. SEILER. Translated from the German by F. W. KEEBLE, M.A. London: J. M. Dent and Co. 1900. Pp. 140. Illustrated. Price 1s.—This little book could hardly be more condensed: in 140 pages it contains as many facts relating to physiology, anatomy, and hygiene as in less able hands could well be spread over three volumes of the same size. The subject-matter is, however, presented in such an attractive and interesting form that the reader is by no means conscious of the degree of condensation until he takes stock of the knowledge which he has acquired by the perusal of the book. From beginning to end it would be most difficult to detect an unnecessary or redundant sentence, and the authors have evidently been at great pains to reject controversial and theoretical matter and to emphasise only established facts and necessary essentials. The first part is divided into seven chapters, which deal in order with the Skeleton, the Muscles, the Nervous System, Metabolism, Excretion, Temperature, and the Larynx. The reason for the separation of the larynx from the organs which are usually arranged in association is not altogether evident, and wedged in as it is between chapters on Temperature and tables of chemical constituents it tends to upset the continuity of scheme which is manifest throughout the other sections of the work. The second part, which is concerned with the laws of health, is further subdivided into the three following subjects: (1) the Necessaries of Life, (2) Hygiene for Special Circumstances, and (3) the Care of the Body. The importance of applied physiology in the development of mind and body, especially in children, renders this second part particularly valuable for board school teachers and others who have the charge of young persons It is to be hoped that many of those who hold these responsible positions will avail themselves of the opportunities afforded by this little work for acquiring the necessary knowledge in an easy and effectual manner.

The Diagnosis and Treatment of Eczema. By TOM ROBINSON, M.D. St. And., physician to the Western Skin Hospital. Second edition. London: J. & A. Churchill. 1900. 8vo. Pp. 136 Price 3s. 6d.—The differences between this, the second edition, and the first, which appeared in 1887, are very slight; here and there a word is altered or a sentence is added or a phrase is removed, but there is certainly no indication of the extension of our knowledge during the last 13 years. The index has been reprinted without any alteration so that the references to pages are often inaccurate. This is a pity, as it would have been easy to have made it correct. Allowing for these defects it may be said that the account of eczema which this little book contains may prove useful to those who have but little acquaintance with the subject

---

SANITARY INSPECTORS' ASSOCIATION.—A meeting of the western branch of this association was held on Oct. 13th at Tiverton under the presidency of the Mayor. The borough surveyor gave an address on Sanitary Work in Tiverton and the deputy medical officer of health (Dr. R. Shiels) read an interesting paper on Tracing Epidemics. The newly erected isolation hospital was inspected and the members were entertained at dinner by the Mayor.

THE LANCET.

LONDON: SATURDAY, OCTOBER 27, 1900.

WE have this year, as we have in previous years, called attention to the inaccuracy of the Medical Register. We recur to the subject at this season, when the date of publication of the Medical Register for 1901 is approaching, in the hope that the General Medical Council will use every means in its power to make the official roll of the profession correct and reliable—a task in which it is the duty of all medical men to give assistance. For we have always allowed that the responsibility for the inaccuracy of the Medical Register lies in the first instance on the side of the practitioners who do not keep the Registrar adequately informed concerning their addresses and qualifications. The Registrar prints yearly "important notices" at the beginning of the Register urging on practitioners the duty of giving immediate notice to the Branch Registrar by whom they were registered of any changes in their addresses and the advisability of registering their full qualifications. But his words go unheeded. For many years medical men agitated for an authoritative or official list that the public might find in it the correct names and styles of all persons duly instructed in the healing arts and might no longer have an excuse for recourse to quacks. Yet now that the machinery exists for the compilation and publication of the list many medical men take no steps to have their names correctly entered upon it. We recommend the penalisation of the indifferent in the manner provided for by the Act (*vide infra*). Allowing, as we do, that the blame for a great part of the present unsatisfactory condition of the Medical Register rests primarily with the medical profession, we think that the General Medical Council would be well employed in bringing the fact home to the profession.

But in the case of a large group of errors the fault cannot be said to be with the medical profession—we refer to the inclusion of the names of dead persons upon the Register. A dead man cannot communicate with the Registrar and the General Medical Council might here take the initiative. The following table is a list of dead persons whose names are to be found upon the official list of the medical profession for 1900. The list does not claim to be exhaustive—indeed, the Medical Directory for 1900 contains in its obituary list for the year 58 other names the owners, or late owners, of which figure in the current Medical Register as living—but it is as nearly correct as we have been able to make it and the General Medical Council is welcome to the information which the table contains. In the third column are references to the publication of obituary notices of the deceased. In many cases similar notices have appeared also in the *British Medical Journal*. We do not think that our contemporary's files or our own can be regarded as inaccessible to the General Medical Council; and after the death of a member of the profession has been announced in the columns of either journal it might be well if the Registrar obtained

Names of Deceased Medical Men retained on the current Medical Register (1900).

Name.	Date of death.	Reference to published obituary.

corroboration of the correctness of the information by sending a registered letter to the latest official address of the practitioner in question. The Medical Act (1858) Clause XIV. runs as follows:—

> XIV. It shall be the duty of Registrars to keep their respective Registers correct in accordance with the provisions of this Act, and the orders and regulations of the General Council, and to erase the names of all registered persons who shall have died, and shall from time to time make the necessary alteration in the addresses or qualifications of the persons registered under this Act; and to enable the respective Registrars duly to fulfil the duties imposed upon them it *shall be lawful for the Registrar* to write a letter to any registered person, addressed to him according to his address on the Register, to inquire whether he has ceased to practise, or has changed his residence, and if no answer shall be returned to such letter within the period of six months from the sending of the letter it shall be lawful to erase the name of such person from the Register; provided always that the same may be restored by direction of the General Council should they think fit to make an order to that effect.

It seems to us clear that it is the duty of the General Medical Council to communicate with persons whose names are on the Register and whose deaths are announced in the medical journals, in the *Times* and other important daily papers, in the Dictionary of National Biography, and in a semi-official publication like the Australasian Medical Directory. Nor can we see that to do so would entail much work upon the secretarial staff of the Registrar. How the Registrar is to comply with the Act by sending a registered letter to the following gentlemen we admit that we cannot suggest:—

Duncan, James.
Foster, Thomas.
Forbes, William.
Blanchard, David.
Williamson, Walter.
Montgomery, R., L.R.C.S., 1829.
Osborne, John Hy.
Nussey, Thomas John Hartley.

for their only address on the Medical Register of 1900 is "Australia." We grant that the Registrar is in a difficulty, but the difficulty has been made by the General Medical Council in accepting such loose entries. The door to flagrant impersonation that has thus been opened wide should be closed immediately.

There is another class of names upon the Medical Register where we think the Registrar might well send the registered letter in accordance with the Act. The following names in the Medical Register of 1900 (and, again, our list does not claim to be exhaustive) are those of gentlemen who if they are still alive must be so advanced in years that they could only take an inquiry into the matter as a compliment:—

Lawson, George McF., M.D.Edin., 1818
Moon, Robert Henry, L.S.A., 1821.
Tinn, George, L.S.A., 1824.
Toulmin, Abraham, M.R.C.S., 1817.
Smith, Charles, L.S.A., 1818
Murray, Thomas, M.D. Edin., 1823.

If Mr. TOULMIN and Dr. G. McF. LAWSON are still alive they must be well over 100 years of age, in which case we congratulate them upon their longevity.

* * *

AT this time of the year, when a number of young students are entering upon studies which will, they hope, render them responsible in the future for the health of their fellow-citizens, it is as well to take a broad view of the medical student's career and with a bird's-eye glance over the whole field to try to notice a weak spot. The satisfaction with which we may thus regard modern medical education is very great if we compare it mentally with that of even only a few years ago. When we make this comparison, however, and particularly if we compare our own day with that of, say, our great-grandfathers, one reflection arises that may ruffle our general content. Are we to-day taught practically enough? With the enormous strides in scientific education, with the additional knowledge in physiology, chemistry, and bacteriology that our students now acquire, does there exist a proportionate increase of skill in the actual practice of their profession. To discuss this question in full would be too extensive an undertaking and we propose to limit ourselves to the consideration of one important art which in practice almost every medical man must at some time or other be called upon to exercise. We allude to the administration of anæsthetics. There is probably no branch of his profession in which the average medical man, whether in town or country, is more likely to be required occasionally to exercise such skill as he may have, and there is certainly none in which a deficiency of skill may more easily have unpleasant if not disastrous results. Medical practice is carried on largely with drugs that cannot do harm within pretty wide limits of dosage, surgical practice devolves chiefly upon those whose skill is in constant exercise, *but anæsthetisation where only potent and dangerous* materials are of use is demanded at times of every medical man.

There can be no case, then, in which knowledge and experience are more desirable in a medical man than in this, which is both of a critical nature and of common occurrence. In large centres, of course, there are plenty of men who devote themselves to the administration of anæsthetics whose wide experience reduces risks to a minimum and whose services are available for surgeons and general practitioners. But, taking the country as a whole, a large proportion of anæsthetics are administered by those whose experience in the matter must of necessity be occasional only. For such men to be proficients in the art is obviously impossible. For them to be safe exponents of it it is essential that they should have been well trained in its principles and in its practice. Do the vast majority of medical students obtain such a training? That it is available for them a mere glance at the prospectuses of the chief medical schools assures us. At almost all of them there are anæsthetists of experience whose duties are not solely to administer anæsthetics for the surgeons but also to deliver lectures and to instruct students practically. Unfortunately the mere fact that excellent opportunity and teaching are at hand is not always enough to induce a student to learn. It is not that he is inherently indifferent. The average student of to-day is keen and eager in all that pertains to his medical education, but the measure of his keenness must largely be the examination value of the subject on which it is exercised. The immediate object of his existence is to pass examinations—to "get qualified" is the *Ultima Thule* of his present ambitions. The market value of a sound knowledge of anæsthetics as an asset at the examination hall is practically *nil*. The subject is not even one for which it is essential that he should be "signed up." Now, there follows from this a corollary which still further lessens any eagerness which a student may feel towards proper education in anæsthetics. Since the examining bodies apparently think little of the importance of the administration of anæsthetics the medical schools, which naturally take their cue from these bodies, cannot insist upon much attention to the subject. Consequently, at many medical schools there is no formal necessity for a student ever to obtain instruction in the matter. At many schools a student must give evidence of proficiency in administering anæsthetics before he is allowed to hold a resident appointment, but even this is not everywhere the case. Moreover, the number of students who become resident officers is necessarily but a small proportion of the whole. At hospitals which have no medical schools attached to them it must often happen, as it assuredly does in private practice, that a man administers an anæsthetic without ever having watched such an administration with care or with the purpose of learning therefrom the dangers to be avoided and the principles to guide him on the path of safety. There is one inherent difficulty in the proper teaching of the way in which to give anæsthetics to all students. This lies in the practical nature of the matter. A student may attend all the lectures available and read all the books, but until he has himself given an anæsthetic he can never become a safe anæsthetist. Now it is impossible for all students at a large school actually to give anæsthetics, under the supervision, of course, of their teachers, except to a very small extent. Even this small extent, however, is of great importance, for if the principles have been already acquired a student need not many times administer anæsthetics under skilled supervision to become a safe administrator, in all ordinary cases at any rate. In cases where a patient about to undergo an operation is seriously ill, or where the nature of the operation offers particular difficulties to the anæsthetist, then a man of only occasional experience in the matter should not undertake the administration, unless, of course, he alone is available.

Having regard, then, to the importance of proficiency in the use of anæsthetics in the after-welfare of the great majority of medical students we strongly urge them to avail themselves of the opportunities offered at their schools. May we suggest to those in authority over them that perhaps regulations requiring some attention to the matter from all students, whether candidates for resident appointments or not, would be of advantage to the medical practitioner of the future and an additional guarantee of the public safety.

◆

DR. OSLER has found time, in spite of all his labours in the study and practice of medicine, to go more deeply than most previous historians of LOCKE into an investigation of the relations of that great man to medicine. LOCKE'S work in philosophy and in the vindication of liberty has been so important that we have been too apt to overlook and to forget his connexion with our profession. It has been left for a physician living more than two centuries after him, and himself at the very front of modern medicine, to remind us of that connexion forcibly. By careful study of manuscripts in the British Museum and of notes and journals wherever accessible DR. OSLER has now shown that in LOCKE English medicine had potentially another SYDENHAM, and that the well-known intimacy between these two great men was, as was the friendship of JOHN HUNTER and EDWARD JENNER, based on likemindedness and on the rich possession by both of large endowments of common-sense and the faculty of close and careful observation. The love of medicine, if not the first love of LOCKE, was a very early one and was one that never forsook him. The distractions were many. Love of letters, foreign travel, intimate relations with the foremost statesmen and men of science of his day, study of the moral and mental constitution of men, delicate health—none of these ever really estranged him from an interest in medicine, though they drew him finally from the practice of it. And we are proud to think that the world is much indebted to his medical knowledge—or, if we may so say, to his medical mind—for the common-sense which characterises his philosophy and which is apparent in every page of his greatest work. DR. OSLER'S address is so full and so original as a contribution to the study of LOCKE as a physician that we may assume that it will be carefully studied by the medical profession. We shall do well to follow the example which DR. OSLER sets us and individually to study for ourselves the working of such a mind as LOCKE'S in the matter of medicine. We shall all be better practitioners for studying his reasonings and experiments, remembering that he not only followed and appreciated SYDENHAM but that SYDENHAM appreciated him and discussed with him the great problems of disease in individual cases, including LOCKE'S own, in respect of which he wrote to LOCKE affectionately, "and with the same intention of mind as if my life and my son's were concerned therein."

In the few remarks which we make by way of emphasising our gratitude to DR. OSLER and our own pride in the fact that his hero really and historically belongs to the medical profession, we do not follow so much the line of DR. OSLER'S address as indicate in a few sentences the points which appear to us to be of greatest interest in LOCKE'S medical character and history. It is important to notice that, like many other great medical men, he was for the greater part of his life more or less a patient. He had a frail body. He suffered from what some of his biographers called "consumption and asthma." In the middle of his life his illness compelled his absence from England for years. Doubtless this made him more sympathetic and helpful as a physician. No complaint was too humble, no remedy too simple, for his thoughtfulness. "Costiveness," equally with consumption, exercised his reasoning faculty and led him to the application of physiological principles for its relief supported by personal experience. Notwithstanding that he was so delicate he contrived to keep his frail tenement together and in pretty active occupation to the age of 72 years and to leave the world richer in wisdom and freedom and virtue for all time. He was also successful in preserving his historical patient the first Earl of SHAFTESBURY in spite of his "imposthume," or, as we see it, his hydatid of the liver, the history of which extended over years, and he conducted him to recovery with a minuteness of care which is well illustrated in the medical notes and journals unearthed by DR. OSLER. Secondly, LOCKE was no specialist. His study of medicine was broad, and it included the cases of men, women, and children. His book, "Concerning Education," shows how deep was his interest in health and in those principles of health or hygiene which need to be intelligently appreciated by those who have children or the care of youth. Whether his patient were the Earl of SHAFTESBURY, the kitchenmaid of the Earl, or one of the children of his friend "EDWARD CLARKE of Chipley, Esq.," or Lady NORTHUMBERLAND, he brings to bear on all their cases his experience and his common-sense Dr. OSLER justly observes on the care with which he reported and recorded cases. The notes of the Earl of SHAFTESBURY'S case could scarcely be exceeded for their detail in our present time, save in so far as improved means of investigation have made a difference.

Most important of all in LOCKE'S system of medicine was the use of strong common-sense and of all the aids that a study of the fundamental sciences could give him. His friendship with BOYLE, with the other founders of the Royal Society, and with the scientific set—"the invisible college"—in Oxford, at once showed and encouraged the openness of his mind to all improvements and enabled him to do great service to his patients and to vindicate his friends, especially SYDENHAM, against the almost intolerable hostility with which their improvements in medical practice were met by many of their contemporaries. He was the forerunner of ACLAND and those of later years who have saved Oxford from being lost in the mazes of theology and who, while retaining the principle of reverence, have raised it above all mere human dogmatism and conceit His practice of physic seems, for his day, to have been eminently sensible. He was a sanitarian and took great pains to study the public health as shown in the mortality bills of great cities at home and abroad. He had a few prejudices that would shock some of our modern physicians—such as that against certain kindly fruits and that in favour of exposing children to cold, with imperfect shoes that should keep their feet continually damp and uncomfortable—but those who lived according to the general trend of his medical rules would live well. He enjoined one meal of meat a day and plenty of bread ("imputing a great part of our diseases in England to our eating too much flesh and too little bread"), and extreme moderation in wine and strong drink, allowing only small beer, and a hard bed. Physic was to be used sparingly and nature was to be much trusted. These are instructions rather for the care of children, but they are meant to lead up to a hardy and virtuous manhood to be possessed on the same principles. For LOCKE held that "the great Principle and Foundation of all Vertue and Worth is placed in this: That a man is able to *deny himself* his own desires, cross his own Inclinations, and purely follow what Reason directs as best, tho' the appetite lean the other way." Such were the medical views of the great philosopher of the seventeenth century whose general wisdom was such that men like SHAFTESBURY and SOMERS consulted him in the affairs of State as SYDENHAM and MAPLETOFT consulted him in questions of medicine.

◆

IN an article in THE LANCET of Oct. 20th (p. 1125) Mr. R. HAMILTON RUSSELL, F.R.C.S., of Melbourne raises, not for the first time, a very important practical question—no less than this, whether every child, except young infants, the subject of inguinal hernia should not be submitted to operation. What we may call the orthodox view is that the great majority of such cases are cured by the persistent use of a well-adjusted truss. All are agreed that by this treatment continued over a period of years the parts may become so altered that even under severe strain no hernial protrusion will occur. And it is contended that this fact justifies the use of the word "cure." It is maintained that under the pressure of the truss the sac is kept emptied, that its natural elasticity is able to exert its effect in reducing its size, and that the pressure may either set up an adhesive inflammation in the sac and so obliterate it, or that it acts as a local stimulant and excites that nutritive change which normally obliterates the funicular process of peritoneum—a change which has been arrested in cases of hernia. Under the empty condition of the sac the fibrous structures around it are freed from distension and displacement and become strong and efficient supports of the inguinal canal.

Mr. RUSSELL inferentially admits that the obliteration of a hernial sac may occur in a young infant, and, so far as we are aware, no surgeon of experience has yet urged that such *an event never takes place. It would seem certain that* nature has the power to accomplish quite soon after birth the obliteration of the funicular process which should have been perfected before birth. This is a mere delay in the normal development of the parts. A very large number of infants are found to have inguinal hernia or hydrocele in an unobliterated funicular process of peritoneum, and the large majority of them appear to undergo cure without surgical operation. Mr. RUSSELL'S contention is that while this may happen during infancy it never occurs in childhood or later. If the natural closure and shrinking of the tube of peritoneum is arrested it is not effected by the pressure of a truss or by any means which merely keeps the sac empty for a period of months or years. The evidence on this point is partly clinical and partly pathological, and is certainly not conclusive. Clinically we find that boys and youths, after wearing a truss for many months or a year or two, often show no trace of their former hernias, and even after all the tests of straining that are usually adopted there is no protrusion into the inguinal canal. If the truss is discontinued they are able to pursue an active life without re-descent of the hernia. But in a certain number of these cases a sudden descent of the hernia occurs at some subsequent period. We are all conversant with cases where after two, three, or more years of freedom from hernia it suddenly recurs, showing that the sac has not been obliterated but is only empty and probably narrowed at the neck. Again, there are very many cases of inguinal hernia which suddenly appear during adolescence or early manhood in which there is no ascertainable history of infantile hernia. The sudden descent of the hernia into the scrotum proves that there was a sac ready formed into which the bowel or omentum could drop as soon as it passed the barrier at the neck. The occurrence of what Mr. FURNEAUX JORDAN well-named "water-bottle hydrocele" also shows that a peritoneal sac may become very narrow at the neck and remain for many years quiescent without yielding any sign of its presence, but yet form a serous sac into which a hernia may possibly be forced. Pathologists, too, know that in patients who give no history of hernia a hernial sac or an unobliterated portion of the funicular process of the peritoneum may be found. We may therefore say that it is indubitable that a potential hernial sac may exist for years without any evidence of its presence, and the mere fact that under the ordinary tests no hernial descent occurs is no proof that a sac does not exist, still less is it a proof that a sac known to have existed formerly has become obliterated by the pressure of a truss.

This, however, does not bring us quite to the position advocated so earnestly and so ably by Mr. RUSSELL. For if men may go on for years with a patent hernial sac, without descent of bowel or omentum into it, it is evident that there is another element in the causation of hernia than the mere presence of a sac. This seems to us the weak point in Mr. RUSSELL'S case. The neck of the sac may become so narrowed that this affords a great if not insuperable barrier to the descent of a hernia, and the valvular action of the inguinal canal may be so efficient that nothing can escape down the canal even although there is a patent sac. We consider that Mr. RUSSELL does not attach sufficient importance to the defects in the muscular and aponeurotic walls of the inguinal canal which certainly play some part even in the hernia of children. While, therefore, we think that most surgeons will quite concur in his view that trusses do not often cure hernia (after infancy perhaps) in the sense of leading to an obliteration of the peritoneal sac, the evidence is too strong to be set aside that in many cases there is no future descent of the hernia into the still patent sac. And if this is so, many surgeons will hesitate to urge operation upon all these patients but will wait until the hernia has again declared itself. There is, however, no finality in surgery, and Mr. RUSSELL has done good service in calling attention to a very interesting and important subject.

Annotations.

"Ne quid nimis."

BRITAIN'S FAITH IN HER SANITARY SYSTEM: AN APPRECIATION.

IN view of the limitation of our knowledge as to the behaviour of bubonic plague it is not our intention to take upon ourselves the mantle of prophecy and to predict that, even for the present, the plague has receded from our shores. Our respect for the unknown future precludes any such liberties. The history of plague warns us that its waves may have, like the cardiac rhythm, their periods of systole and diastole, and that the disease may, in its general progress, wax and wane. For aught we know to the contrary, material from one or another of our ports may be at this moment undergoing examination in the laboratory, and the passing away of an inoculated guinea-pig may, before these lines are read, have been instrumental in announcing to certain signatory powers, in accordance with the provisions of the last Venice Convention, that fresh cases of pestis minor or major are with us. But whatever the port medical officer of health or the bacteriologist may have in store for us we are concerned at this moment with a little appreciation of the past. The public is not accustomed to enter into a very detailed analysis of its feelings, be they of apprehension or of security, but the presence or absence of such feeling is sufficiently obvious in the public press, when a national danger threatens. With respect to plague prevention there is only one conclusion to be drawn as to the public opinion of this country and that is that it places implicit confidence in the system by which the introduction of exotic diseases is checked; indeed, there are signs that the public may ere long look with only little more anxiety upon an occasional case of cholera, yellow fever, or plague, than upon one, say, of small-pox. This faith in our system has been gradually and imperceptibly brought about by the admirable manner in which the more or less desultory bombardment of our coasts by plague and cholera within recent years has been met. It has been met by a system which these islands may well view with satisfaction, and which is being slowly accepted by European Powers, and, in principle at least, by countries outside Europe. The proper appreciation of this system by Britain and the partial recognition of its merits by other Powers, have been very largely due to the indefatigable efforts of successive medical officers of the Local Government Board, and more particularly, perhaps, to the powerful advocacy of the late Sir Richard Thorne at the several international congresses at which he represented Great Britain. For the present organisation of the machinery our thanks are due to the foresight and energy of the Central Health Department, the medical staff of which devotes no small amount of thought and action towards its share in administration. But the smooth working of the machinery, under the system of local government which obtains in Britain, would be practically impossible without the cordial support of the port sanitary authorities, and in this connexion it is gratifying to record the admirable example which has been, and is being, set by the liberal and rational spirit in which the sanitary authorities of ports such as London, Liverpool, Manchester, Southampton, and Plymouth have met their responsibilities, and have, where necessary, cooperated with the Government departments concerned with the movements by sea of our small but migratory army. It is to our port medical officers throughout the country, embracing in this term those who serve as assistants or inspectors, that no small meed of praise is due. Only those whose duty it has been to board and to examine vessels in all conditions of weather, to harangue obstructive skippers in languages not their own, or to diagnose a suspicious case of plague in the stuffy and ill-lighted forecastle of a small steamship, can appreciate the enormous responsibilities of the port medical officer or estimate what the country owes to him. So, too, those who are unfamiliar with the difficulty of dealing with an outbreak of disease without means of proper isolation and disinfection can have no idea of the anxieties with which an inland medical officer of health faces the presence of a disease like bubonic plague in his district. Fortunately, in a sense, we shall have now before us the excellent example set in Glasgow by its able medical officer of health, Dr. A. K. Chalmers; and the near future may show the desirability of carefully studying the Glasgow methods in order that certain sanitary authorities south of the Tweed may ascertain how their own districts would fare in presence of an invasion such as has visited Glasgow. That outbreak teaches us the immense importance of seeking out suspicious cases and of isolating them until all risk be past as well as the necessity for isolation provision and accommodation for "contacts." The sooner the more negligent of our authorities see to these points the better for them and for the country.

A NOBLE DEATH.

WE are rightly proud of the fact that the medical profession numbers many heroes among its ranks. It is no uncommon thing for a medical man to lay down his life owing to the exigencies of his profession; but the recent death of Mr. Alexander Stewart Brown, F.R.C.S. Edin., which took place on Oct. 17th, deserves special recognition owing to the circumstances which led up to it. A week or two ago Mr. Brown met with a carriage accident in which he injured his spine. In order to recruit his health he set out for the South of France and on arriving at Boulogne he was just getting into the train when he saw a young man with whom he had travelled from London fall off the quay side into the water. Mr. Brown at once waded into the water nearly up to his neck, got the man out, and finding that he was unconscious, wet as he was, proceeded then and there to perform artificial respiration. After two hours' hard work Mr Brown was successful and he continued his journey to Paris. When there, however, he became so ill that he thought it best to return home, which he did, but succumbed to pneumonia shortly after his arrival We cannot call the circumstances of his death sad, for if there is one desirable manner of death it is that which is incurred in saving the life of a fellow-creature, but none the less we offer our sympathy to Mr. Brown's relatives and friends. He was a well-known figure in the municipal life of Lewisham and was also a prominent Freemason.

MEDICAL MEN AND THE MORPHIA HABIT.

THE *Medical Temperance Review* for October contains a short paper on Morphinism among Physicians. If we are to credit the writer the habit of taking opium and allied drugs is more or less prevalent among from 6 to 10 per cent of medical men. The statement is a vague one and no precise data are advanced in support of it, though the reader is referred to a former report dealing with this subject. It would be better for all purposes if a paper of this kind, which contains only the most general assertions, were elucidated by verified details; lacking these its value cannot be estimated or even recognised. It would be idle to deny that medical men, like all other men, are occasionally liable to propensities which do not make for their advantage and from which not even a knowledge of the action of drugs can always deliver them. On the other hand, indefinite assertions like those contained in this brief paper cannot be accepted without those proofs which are absent from it. That accidental opium-poisoning has repeatedly cut off a useful professional career is unfortunately true. Little more than a week has elapsed since a medical practitioner died at Bolton, Lancashire, from the effects of an excess of opiate which was taken to procure sleep. But a morphia habit which controls one in every 10 or 20 men is certainly not known to exist in the medical profession. Such a habit, if it does exist, must be quite exceptional It is probably unknown among practitioners engaged in active duty. We observe that the writer above-mentioned speaks of the morphia habit as if it were merely a disease and nothing more. It has become customary with many persons to refer to this and other aggravated forms of self-indulgence in similar terms. They are regarded as vices which have ceased to give pleasure, as master-passions which are hated, but which will not be denied Against this tyranny the will is supposed to have lost its power of resistance. There are doubtless cases of habitual excess the character of which is fairly so described. We are of opinion, however, that too much has been made of such cases It cannot be, and it is not, true that a vice even after long indulgence is always master and cannot be withstood. It is equally certain that apparently confirmed inebriates and morphia-takers have been enabled to release themselves and have remained in a state of freedom. The force of habit whether innocent or hurtful is usually very great, but this by no means implies that it must necessarily even after long duration annihilate the other controlling force of will. To what extent it may have done so remains in many cases an unsolved problem and in this very uncertainty lies the germ of hope. Unless we recognise this patent fact, all prospect of reform, all reason for the efforts of temperance even may be abandoned. No amount of therapeutics will make a bad man good or a drunkard abstemious unless he is allowed credit for such will power as he has and is assisted or obliged to use it for his moral reclamation. While therefore we do not deny the existence of the states known as dipsomania or morphinomania, we deprecate as pessimistic and subversive of rational treatment the too general tendency to apply these and like terms to all aggravated cases of self-indulgence.

THE INSANE JEW.

IN the October number of the *Journal of Mental Science* Mr C F. Beadles of Colney Hatch Asylum gives an account of the Jew in so far as he is liable to insanity, the records of cases which form the basis of his paper being taken from the London County Asylums and from other sources An examination of 1000 cases has revealed certain salient features regarding the insane Jew. First and foremost is the abnormally great preponderance of general paralysis amongst the men. Thus, reckoning on the admissions, it is found that over 21 per cent. of all male Jews admitted were the subjects of general paralysis, whereas the general proportion of general paralytics in all males admitted to asylums in England and Wales is (according to the report of the Commissioners in Lunacy for 1899) 13 per cent. Among the Jewesses the proportion of general paralysis is that of the females admitted generally throughout the country. It is thus evident that amongst the Jewish male admissions general paralysis is 60 per cent. more frequent than among other English and Welsh patients admitted to county and borough asylums. Mr. Beadles states that inquiry as to the relative prevalence of syphilis in the Jewish community is beset with difficulties, but that there is ground for belief that "syphilis is fairly frequent, though doubtfully to the same extent, as amongst the population in this country at large" Considering the fact that syphilis plays a most potent part in the production of general paralysis the need of accurate statistics is obvious. Drunkenness is said to be "less common among the poorer Jews than is the case amongst the lower classes of English On the other hand, sexual excess figures in high ratio as an assigned cause for insanity (among Jews)." It is shown that the mental strain resulting from the worry, anxiety, and excessive zeal in acquiring riches, plays an important part in bringing about neurasthenia and mental breakdown in the Jew. In hospital and private practice it is often found that the Jewish male is neurotic and that the Jewess is a sufferer from hysteria. "Hereditary insanity probably figures high in the race, but it is impossible to get at the proper proportion" The average age at which Jews become insane is distinctly earlier than in non-Jews, and this holds good for both sexes. The average age of admission for Jews into the London County Asylums was 37 years and that for Jewesses was 35 years, whereas the average age of all admissions into the London County Asylums in 1898 was 43 years for both men and women. The ages at death bear somewhat similar proportions. Male Jewish patients died at the age of 44 years and Jewesses at 47 years, whereas the other London County

Asylum male patients died at the age of 51 years and the female patients at 55 years. Jewish patients discharged from asylums relapse twice as frequently as all other patients. While general paralysis was relatively common among Jewish males puerperal insanity was prevalent in a high proportion among the Jewesses who were admitted to asylums. "In over 15 per cent. of all Jewish female individuals admitted to the Colney Hatch Asylum the insanity was traceable to, and associated with, child-bearing," whereas in non-Jewish patients the proportion was 6·18 per cent. in all the London County Asylums. Mr. Beadles finds an explanation of this in "the neurotic temperament of the Jewish women, the early age at which marriage takes place, together with impaired nutrition from unhealthy occupations and surroundings in overcrowded centres." Over 80 per cent. of Jewish patients or their parents were found to have been born abroad. They mainly come from Russian Poland or from German States. The impoverishment and stress of living which many of these have experienced before reaching this country have helped to wreck their nervous systems. It is also concluded that Jewish patients furnish the most troublesome, degraded, and refractory of chronic and incurable cases in asylums.

DISINFECTION OF THE HANDS.

CONTINENTAL surgeons have taken up the question of disinfection of the hands very zealously, but it cannot be said that as yet any definitive solution of the attendant difficulties has been arrived at or even that methods which yield good results with one observer have been found equally efficacious by others. In a paper published in the *Archiv für Klinische Chirurgie*, 1900, p 463, Dr. Sarwey has given an account of some experiments which he and Dr. Paul have conducted with regard to several of the most prominent systems. Investigators vary, they found, not only as to their modes of procedure, but also in the way in which they test the efficacy of the measures adopted. Hagler of Bâle, for instance, rubs the disinfected hands with spun silk which is then tested for germs, while Kümmell steeps the extremities themselves into the nutritive media. The method of control preferred by the experimenters is that of Fürbringer, which consists in thoroughly scraping the hands back and front as well as between the fingers and round about and under the nails with sterilised pieces of wood of various shapes and sizes. Before proceeding to examine the more complicated systems of disinfection of the hands Dr. Sarwey and Dr. Paul tried the effects of vigorous brushing with soap and hot water, the brush, the soap, and the water being sterilised and renewed six several times, and the whole operation being prolonged over 35 minutes. A scrubbing of this severity, we might *a priori* suppose, should suffice for the removal of the most tenacious of microbes, to say nothing of the subject's epidermis, but Pétri's boxes sown subsequently with hand-scrapings were nevertheless found to be swarming with germs. The system of Ahlfeld, which is based on hot water and alcohol, was then essayed, with a somewhat more satisfactory result; but although the germs were found to be diminished in "notable proportions" they were not completely removed. The system advocated by Mikulicz was next investigated. According to it the hands to be disinfected are rubbed assiduously for five minutes with an alcoholised soap, all greasy matter having previously been got rid of by means of pumice stone steeped in alcohol. After a series embracing 12 repetitions the conclusion arrived at regarding this process was that although, as in the preceding method, the germs were greatly reduced in number there was always a more or less considerable residuum left behind. Lastly, the "mechanical disinfection" of Schleich was put to the test. The chief peculiarity of this system is the entire abandonment of the nail-brush, reliance being placed exclusively upon a special kind of soap which is made with wax and powdered marble (*wachsmarmorstaubseife*). It is claimed by the inventor that after 15 minutes of energetic friction with this compound in sterilised water (constantly renewed) the hands to be disinfected are freed from at least 97 per cent. of their germs, but Dr. Sarwey and Dr. Paul were unable to obtain anything like so good a result. On the contrary, notwithstanding their utmost care, so abundant were the germs which they found remaining that it was quite impossible to look upon the hands that had been operated on as sterilised. The explanation of this regrettable divergence of opinion is doubtless to be found in the mode of control adopted. Schleich used platinum rods to collect germs from the main parts of the hand only, dipping the rods when charged into gelatin tubes which were kept at the ordinary temperature of the room; whereas Dr. Sarwey and Dr. Paul, adhering to Fürbringer's method of collection as above described, made their cultures on agar in Pétri's boxes which were kept at a temperature of 99° F. On the whole, the conclusion to be drawn from these interesting experiments would seem to be that alcohol and soap with hot water are capable of largely reducing the number of the pathogenic germs which are located on the hands, but that as yet no method of ensuring absolute sterilisation has been devised.

UNREGISTERED PRACTITIONERS AND DEATH CERTIFICATES.

AN inquest was recently held to inquire into the cause of death of a man who had died at Dewsbury after being attended by a person calling himself "Dr. Haworth," whose name is not upon the Medical Register. This gentleman describes himself upon his doorplate as an "M.D. of Canada," and the registrar of deaths had declined to accept his certificate, in which, we believe, the cause of death was described indifferently as "hemorrhage" and "hemorage" of the lungs, the registrar's refusal having as its natural result an inquiry before a coroner's jury. "Dr. Haworth" has addressed to the local press a letter of protest, from which we give extracts, directed against the registrar on account of his action in the matter, and he states that he will follow it with a second dealing with the coroner. He writes:—

> "With respect to my late patient's death and the cause why our Registrar did not register it I have yet to learn. I am a duly qualified M.D. and C.M. of Canada ...... Registration in Great Britain is no evidence of qualification, and being unregistered indicates no lack of skill or ability to cure disease or injury. As a matter of fact the finest and most successful physicians in this country are those who have been educated abroad, and hold foreign honours. There is no more cause for our Registrar refusing to register the death of my last patient than the previous ones, and the fact of his having registered four before is of itself evidence that he ought to have registered this. I have seen him on the subject and he says that all future cases will be reported to the coroner ...... I not being a registered practitioner give a form of certificate used by all medical reformers, and which is received by the Registrar-General as part information of the cause of death. ...... The one reasonable excuse for a Registrar refusing to register a death is its being caused by accident or suspicion of secret murder, or other foul play."

We congratulate the Dewsbury registrar on the resolution which he has announced, and in support of the position which he has taken up rather than with any idea of correcting or convincing "Dr. Haworth," we point out that registration is direct evidence of qualification to pronounce upon the cause of death, while the absence of registration implies the absence of such qualification, if it does not directly prove it; so that a registrar who accepts the so-called certificate of an unregistered practitioner, whether it be given in a form "used by all medical reformers" or not, undertakes a heavy responsibility. From this responsibility he is free if he confines himself to registering deaths only when they are certified upon the official form issued to registered medical practitioners and to no one else, whereas any such practice as that of treating the certificates of the unregistered as "information" is one against which we protest on the ground that it is dangerous to the public. Again, registration is not to be refused only where there has been an accident or where foul play is suspected, but where there is any doubt as to the cause of death. If "Dr. Haworth" has really "yet to learn" the cause of his certificate not being treated as establishing the cause of his patient's death, we may suggest to him that since the registration of the other deaths he mentions it may have struck the registrar that Canada is not a university, and that the description "M.D. and C.M. of Canada" is consequently somewhat indefinite; while he may upon reflection have come to the further conclusion that certificates which may possibly without illegality be treated by a registrar or by a coroner as containing information may at the same time be destitute of any that a prudent man would rely upon.

THE LATE SIR HENRY ACLAND.

THE remains of Sir Henry Acland were interred at Oxford in a grave beside that of his wife on Friday, Oct. 19th. The Prince of Wales sent a wreath of red roses with the inscription "For Auld Lang Syne," and the company which assembled to pay their last tribute to the deceased *savant* was a very distinguished one. In addition to the chief mourners the Royal Society was officially represented by Lord Lister; Oxford University by the Vice-Chancellor and Proctors; Cambridge University by Dr. Clifford Allbutt; the General Medical Council by Dr. J. F. Payne; the British Medical Association by Sir John Burdon Sanderson, Mr. E. Dening (Stow-on-the-Wold), Dr. O. L. H. Pemberton (Banbury), Dr. W. T. Brooks (Oxford), Mr. T. H. Cheatle (Burford), and Dr. W. Collier (Oxford); the Corporation of Oxford by the Mayor, aldermen, and councillors; the Oxford Union Society by the President, Mr. H. T. Baker of New College; and the Oxfordshire Natural History Society and Field Club by Mr. G. Claridge Druce. Amongst others present were Sir Richard Douglas Powell, representatives of the Oxford Colleges, and many representative men in all walks of life. At the conclusion of the first portion of the service, which was held in the cathedral, a procession was formed and the body was conveyed to the cemetery.

A CASE OF SO-CALLED "BROWN-SÉQUARD'S PARALYSIS."

DR. RICHARD WOODS of Philadelphia reports in the *American Journal of the Medical Sciences* for August an interesting case presenting most of the symptoms of unilateral lesion of the spinal cord described by Brown-Séquard, the symptoms being so well marked as to make the diagnosis certain, although the patient came under observation more than one year after the injury The history was as follows. In January, 1898, the patient while leaning over a railing was struck forcibly in the back of the neck with a knife. He fell immediately to the ground and on attempting to rise he found that he could not raise his left leg or left arm. He was dazed but suffered no loss of consciousness. On admission to hospital there were the above symptoms, the temperature, pulse, and reflexes were normal, and he had incontinence of urine. In the fourth week he noticed some restoration of the power of movement in the left hand and during the following week in the left leg. He continued to improve and in the seventh week was able to walk a short distance. The wound in the neck healed by first intention. He was discharged from hospital in two months, being then able to use his left arm slightly and to walk, though in a very uncertain manner, the gait being unsteady and the left leg being dragged in walking. In May, 1899, he went to the Pennsylvania Hospital Dispensary. The knee-jerk was then much exaggerated on the paralysed side, and there was ankle-clonus on the same side. The reflexes in the paralysed arm were also exaggerated. The sensory alterations were very similar to Brown-Séquard's description and were as follows. In the paralysed leg tactile sensibility was increased over the whole limb (hyperæsthesia), while in the non-paralysed leg it was greatly diminished. There was hyperæsthesia to painful stimuli in the paralysed limb, whereas in the opposite limb there was analgesia. Muscular sense was lessened in the paralysed limb but was unaltered in the sound limb. Thermal sensibility was increased in the paralysed limb and lost in the opposite limb. The patient could easily locate a sensory impression in the paralysed limb but could not do so in the non-paralysed limb. In regard to the upper limbs, the alterations of sensibility were similar to those in the legs, with the exception of tactile sensibility which was present on the non-paralysed side, whereas the sensibility to pain was much diminished on the same side. As regards surface-temperature the paralysed leg was much warmer to the touch than the non-paralysed leg, but no change of temperature could be noticed in the arms. The following two points are of special interest. There was loss of motor-power in the arm and leg on the side of the lesion. This was due to the fact that the pyramidal motor fibres were destroyed or severed. There was anæsthesia for all kinds of sensibility (tactile, painful, and thermal) in the leg opposite the side of the lesion. This confirms the original theory of Brown-Séquard that the sensory fibres concerned with those impressions decussated in the spinal cord and passed up along the opposite side of the cord. The loss of muscular sense in the paralysed limb may be correlated with the fact that the muscular sense impressions passed up (along the columns of Goll and Burdach) on the same side of the spinal cord as the pyramidal tract.

LUNACY IN SCOTLAND.

THE forty-second annual report of the Commissioners in Lunacy for Scotland shows that on Jan. 1st, 1900, there were 15,663 insane persons under official cognisance, an increase of 264 over that of the previous year. Of these, 52 were maintained at the expense of the State in the lunatic department of prisons, 2374 were maintained from private sources, and 13,237 by parochial rates, As the average annual increase in the number of pauper patients in the five years 1891-95 was 194, and the increase in the number of pauper patients during 1899 was 235, it will be seen that the latter increase is not a considerable one and that it falls below the increase during the year 1898, which, for causes still unexplained, reached the exceptional figure of 438. Taking, however, quinquennial periods it is found that the average annual increase in the quinquenniad 1895-99 reaches the figure 303 for pauper patients. The number of cases discharged as recovered during the year amounted to 1289 among pauper patients and 250 among private patients. In proportion to the average number resident in establishments during the year, the total recoveries amount to 12·4 per cent. for pauper and private patients inclusive. The total number of deaths among pauper and private patients in establishments during the year amounted to 1099, or 8·9 per cent. as calculated on the same basis. The death-rates varied according to the classes of establishments as follows: in the lunatic wards of poorhouses it was 4·7 per cent., in parochial asylums it was 8·9 per cent., in royal and district asylums it was 9·3 per cent., and in private asylums it was

12 per cent. During the year 186 patients escaped from asylums, and of these all but 20 were captured and brought back within 28 days from the date of escape. Of 93 accidents and casualties which occurred 10 ended fatally, seven of the 10 being due to suicide. During the year 80 private patients were placed in single care and 2703 pauper lunatics were boarded out in private dwellings. The total expenditure for pauper lunatics was £309,356, or £24 2*s* per head.

THE CHARGES AGAINST LONDON HOSPITALS.

A CERTAIN section of the lay press has during the week been attributing ignorance and cruelty of the crudest sort to those responsible for the management, medical and lay, of certain of the London hospitals. Mistakes unfortunately will occur, but those who denounce our metropolitan hospital system are, we are quite certain, ignorant of the number of sick persons who pass through the hands of house physicians and house surgeons and of the proportion of error which results. The proportion is incalculably small, probably less than $\frac{1}{1000}$ per cent. It is unfair as well as grossly stupid to write, as has been done in one or two quarters, as if a certain spirit of inhumanity were innate in hospital management.

ELECTRIC LIGHTING BOARDS.

A VERY decided advance in the incandescent system of electric lighting has recently been made which will add considerably to the convenience and comfort of those using the electric light. By this new method, which is known as he Electric Lighting Board System, an electric lamp may be attached to any part of the wall, ceiling, or table without the impedimenta of sockets, plugs, holders, and a maze of flexible wiring. To switch on a lamp by this system means simply to stick in, so to speak, two pins into a pin-cushion. The electric board may be let into the ceiling or wall or table or floor, and it is only necessary to "prick in" the lamp at any point to obtain the light. The lamps for the purpose terminate in two pin-pricks in place of the usual points of contact which connect the filament with the main wires. Any number of lamps may thus be stuck in the electric board and in any place and the current thus tapped. Instead of plain lamps, standard lamps may also be used with pin-points projecting from beneath the base. The convenience of this system hardly needs pointing out. Everybody is familiar with the difficulty experienced of getting the electric lamp always in the right position. The difficulty occurs in the operating theatre, but by means of the electric board the lamps can be placed in whatever position is required. They can be inserted into the operating table itself. The same system is adapted to strips or cables and a lamp may be placed at any given point and the current drawn off for lighting purposes. Writing tables, again, may be fitted with the electric board and an electric light may be obtained at any point. Mirrors may have their frames fitted with the electric board and lights may be obtained at any point in a similar manner. By means of the electric board also it is easy to obtain definite designs in electric lamps. Thus a word may be easily portrayed on an electric board by placing the electric lamps in such a way as to form letters. All this may be done without wires, sockets, or holders. Many other interesting and convenient applications will occur to different minds, but, in a word, the system may be described as giving the light exactly where it is wanted without any trouble in regard to mechanical fittings at all. A very interesting demonstration of this new and promising system was given at the show rooms and factory of the Electric Lighting Boards Company, [illegible] street, Soho, on Oct. 23rd, when a number of literary and scientific gentlemen watched the new practical experiments with great interest.

THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

THE board of management of this hospital have recently had under their consideration the matters at issue between themselves and the medical staff of the hospital. As a result they passed on Oct. 17th last the following resolution:—

> That, in view of allegations in the [illegible] interests of the hospital, it is desirable [illegible] with held into the charges formulated [illegible] domestic condition and management [illegible] board should request some independent legal authority to conduct such inquiry.

Mr. Burford Rawlings, the secretary-director of the hospital, has written to the *Times* and in the course of his letter arrives at the conclusion that the system of hospital management in vogue at St. Bartholomew's Hospital "in itself disposes of the suggestion that the board [of the National Hospital] have not given full facilities for the coöperation of the medical staff in all matters concerning the medical work of the hospital." We cannot follow Mr. Burford Rawlings's argument, but there can be no doubt of this: if the National Hospital for the Paralysed and Epileptic is to enjoy the public confidence and scientific prestige which it has hitherto enjoyed and to continue its splendid charitable work among a particularly afflicted class of the poor, the board of management and the medical staff must work together. The obvious method for insuring such coöperation is the placing of seats on the board of management at the disposal of the medical staff.

KOPLIK'S SPOTS IN MEASLES.

IN the October number of the *Yale Medical Journal* Dr. W. J. Maroney of Springfield, Massachusetts, publishes a short paper on his experience of Koplik's spots in an epidemic of measles which occurred in the New York Foundling Hospital in March and April. During this period there were 140 cases of measles in the hospital. In 53 cases Koplik's spots were recognised only at the time when the ordinary eruption commenced, but it must here be explained that the large majority of this group of children did not come under medical observation until after the appearance of the eruption. In 51 cases Koplik's spots were recognised 24 hours before the appearance of the ordinary eruption; in all of the 51 cases the temperature was from 99° to 101° F.; in 35 of them there were slight coryza and conjunctivitis. In 20 cases Koplik's spots were recognised 48 hours before the appearance of the ordinary eruption; at this time the patients had slight fever but no coryza. In four cases Koplik's spots were recognised three days before the appearance of the ordinary eruption; these patients had slight fever but no coryza. In two cases Koplik's spots were recognised four days before the appearance of the ordinary eruption; these patients had slight fever but no coryza. In two cases Koplik's spots were observed but there was no eruption; both of these children were very delicate; hyperpyrexia and other symptoms of grave import intervened and death occurred in a few days. In eight cases Koplik's spots were not observed; four of these children were marasmic with very dry mouths; two had aphthous stomatitis covering the mucous membrane. It will thus be seen that in 79 cases Koplik's sign was present before any eruption appeared on the skin. In only two of the 132 cases in which Koplik's spots were observed did the characteristic eruption of measles fail to appear. Dr. Maroney, therefore, considers that Koplik's spots are pathognomonic of measles and enable the disease to be recognised at an early stage. These spots occur on the buccal and labial mucous membranes. They were first described by Flindt in 1884. In 1898 Dr. Henry

Koplik published his account of them in the *Archives of Pediatrics* He described them as "small, irregular spots of a bright red colour; in the centre of each spot is .. ... a minute bluish-white speck. There may at first be only two or three or six such rose-red spots with bluish-white speck in the centre."

"THE CONDUCT OF SANITARY INSPECTORS IMPUGNED."

IN THE LANCET of Dec 16th, 1899 (page 1681) we mentioned that a book entitled "The Revival of British Agriculture" had been published by Mr. Peter Anderson Graham, who had thought fit to make some very remarkable allegations against inspectors who are appointed to collect samples of food under the Food and Drugs Act. He said that they winked at milk adulteration, sent dairy-keepers previous notice of their intended visits, and received cheques from them. Sanitary inspectors, for their part, promptly resented these imputations The next issue of THE LANCET (page 1774) contained a letter signed by four sanitary inspectors for the vestry of Chelsea pointing out that the libel was a serious one and that investigation was urgently required. Mr Graham seems to have maintained an impenitent attitude until he appeared in the Central Criminal Court on Oct 23rd charged with having published certain alleged libels concerning the sanitary inspectors of England in their capacity of inspectors. The prosecution was instituted by the Sanitary Inspectors' Association. No evidence was offered, for the defendant's counsel said that he expressed regret, withdrew all the statements complained of, and apologised. The jury then returned a formal verdict of "Not guilty" and the defendant was discharged. It was cruel of Mr. Graham to cast wholesale aspersions on a meritorious class of public officials and contumelious of him not to retract the same until he was compelled. And such conduct does harm in another way. Mr Graham's ignominious collapse will tend to give genuine evildoers a sense of security.

HERPES ZOSTER WITH A GENERAL ERUPTION

SOME time ago we called attention in an annotation[1] to the "aberrant vesicles of herpes zoster" described by French dermatologists—isolated vesicles found disseminated over the body in cases of herpes zoster and similar herpetic vesicles. In 1898 M. Tenneson, after a careful study of the subject, said that if the entire skin of patients suffering from herpes zoster were examined every day these "aberrant vesicles" would be found in nine cases out of 10. In our annotation we remarked that this statement by the well-known dermatologist of the St Louis Hospital was startling, for these vesicles had never, so far as we knew, been observed in this country Subsequently[2] a correspondent called our attention to the fact that they had been observed in "An Unusual Case of Zona," published by Dr. W. A. Mackay in the *Glasgow Medical Journal* for October, 1897, which appears to have been the only case on record in English medical literature at the time Later, in the *British Medical Journal* of Feb. 11th, 1899 (p 388), Mr. W. L. Ffrench described the case of a man, aged 60 years, who had severe intercostal herpes, constitutional disturbance, and a temperature of 100° F. Scattered over his face, arms, and abdomen were a number of vesicles Varicella complicated with herpes had been diagnosed, but Mr. Ffrench was not satisfied with the diagnosis. Upon reading a description of these "aberrant vesicles" he recognised his case as an example. In the *St. Bartholomew's Hospital Journal* for August two cases of herpes zoster with a general eruption are published by Dr. J. A. Arkwright. In Case 1 a man, aged 23 years, had a typical eruption in five patches—(1 and 2) over the outer half of the spine of the right scapula, (3) an oval patch reaching from the middle of the right clavicle to a point three inches above the nipple, (4) over the biceps, and (5) in front of the right elbow. Scattered over the body were a few spots similar to those constituting the herpetic patches—viz, two papules just below and behind the lobule of the right ear, a vesicle over the middle of the sternum, and a vesicle over the sixth rib. On the third day the herpetic patches were healing, but another vesicle had appeared on the abdomen The herpes was thus distributed in the areas of the clavicular and acromial branches of the supra-clavicular nerves, the circumflex nerve, and the internal cutaneous nerve. In Case 2 a man, aged 60 years, had herpes in nearly the whole area supplied by the ophthalmic division of the right fifth nerve, and in part of the areas supplied by the superior maxillary and auriculo-temporal branches. On the fourth day a general eruption composed of spots like varicella vesicles was noticed Each consisted of a clear vesicle of about the size of a hempseed with a red line round the base. These vesicles were scattered sparsely over the neck, chest, arms, and abdomen There were about 20 in all On the seventh day a few vesicles had appeared on the lower limbs, the temperature being 101 8° F. Convalescence was slow, extensive ulceration in the right frontal and parietal regions took place, and an ulcer formed on the right cornea Dr. Arkwright remarks that the "aberrant vesicles" are difficult of explanation, but Landouzy's hypothesis that herpes zoster is but a local manifestation of a general infection, which we have advocated, at once explains them. If this view be accepted the difficulty lies in explaining the local and not the general eruption. But such a local result from a general intoxication occurs, as is shown by the existence of arsenical herpes

THE LATE MARQUIS OF BUTE AND MEDICAL CHARITIES.

THE late Marquis of Bute during his lifetime was a munificent supporter of hospitals and the assistance he gave, although unostentatiously rendered, was bestowed with no sparing hand. In the year 1881 he established at Aberdare in South Wales an accident hospital with accommodation for 14 patients and the whole cost of the institution has since been borne by the Marchioness of Bute. Two years later Lord Bute erected a cottage hospital of about the same size at Cumnock in Ayrshire, and under the terms of his will his heirs are directed to maintain both these institutions. At Cardiff for many years past H M S *Hamadryad* has done duty as a seamen's accident hospital and excellent work has been done between the decks of this hulk. With beds always occupied and cramped space precluding the possibility of extension there was felt to be a few years ago an absolute necessity for more room and it was decided to erect a building close to the docks, with accommodation for at least 70 patients at an estimated cost of £30,000 Towards this sum Lord Bute offered £10,000 conditionally upon other sums being raised. These conditions were fulfilled, but the managers of the institution were under some anxiety as to their ability completely to carry out their original scheme in its entirety This anxiety has now been removed for Lord Bute has bequeathed a further sum of £10,000 towards the building, provided it is needed. Some concern has been shown with respect to a stipulation which accompanies this particular bequest, which reads: "I further direct and request my trustees upon the said hospital being completed to arrange that the sick received in the said hospital shall be served by sisters of some Roman Catholic religious order, if such an arrangement can be made." In this connexion it may be remarked that hitherto the nursing upon the *Hamadryad* has been almost exclusively performed by male nurses.

"LIQUEURS."

THOUGH the taking of a "liqueur" after dinner may not be a pressing necessity, yet it is probably a physiologically correct proceeding apart from the question of the wholesomeness of the individual constituents of the sweet aromatic spirituous liquid. Liqueurs are, of course, decidedly stimulating and they induce a sense of warmth and comfort after a meal which may mask any feeling of gastric discomfort that might otherwise be experienced. This effect, however, is due to some extent to the spirit, but more particularly it may be referred to the aromatic oils. The oils of aniseed, absinthe (wormwood), cinnamon, caraway, &c, and most other aromatic oils, are carminative and soothing, and therapeutically these come under the general description of stomachics. The liqueur is not necessarily a product of distillation so far as its aromatic ingredients are concerned. The distilled products, however, are probably preferable to mere spirituous infusions from the dietetic point of view. Chartreuse and Benedictine are distilled from a mixture of various natural aromatic substances, many of which, it is said, are contained in the British Pharmacopœia. Kümmel, again, is distilled from caraway seeds and many authorities consider that this liqueur is the most wholesome. The colouring matters used in liqueurs are, of course, added, amongst the substances used being Prussian blue, sulphate of indigo, burnt sugar, spinach or parsley green, cochineal, logwood, saffron, and turmeric. Chloroform, it is said, is often a constituent of liqueurs and internally chloroform has a marked sedative action on the stomach and is an antispasmodic. Amongst other constituents used in the formulæ of liqueurs obtained by simple infusion are aloes, spirit of nitrous ether, acetic ether, and ammonia. It is not to be supposed that the best ingredients are necessarily added, since any imperfections would not be obvious to the palate on account of the powerful nature of the aromatic oils. Certain celebrated liqueurs have, as is well known, an interesting and classic history and the secrets of their manufacture are still most jealously guarded. Doubtless these liqueurs had their origin in the fact that their chief effect was that of a carminative during digestion owing to the aromatic oils.

PULMONARY STENOSIS: A VERY RARE FORM OF CARDIAC DISEASE.

STENOSIS of the pulmonary artery is one of the least frequent of cardiac lesions met with in practice. Dr. A. Kasem-Beck, in a recent issue of the *Centralblatt fur Innere Medicin* (No. 23, 1900), reports a very rare and interesting case of acquired stenosis of the pulmonary artery—a condition that is difficult to diagnose. The case was that of a man aged 50 years who suffered from cardiac trouble, with a systolic thrill felt over the cardiac area and most distinctly perceived in the second left intercostal space over the situation of the trunk of the pulmonary artery. There was a general increase of cardiac dulness and auscultation revealed a marked systolic murmur which was heard over the cardiac area, but most loudly in the second left intercostal space close to the sternum. A slight diastolic murmur was also present in the second right intercostal space and at the middle of the sternum. The pulmonary second sound (associated with the closure of the valves) was not accentuated. From the position and character of the systolic murmur it was at first thought to be due to mitral regurgitation. The patient died, however, and the necropsy revealed a stenosis of the pulmonary artery, the lumen of which was narrow, while the intima was rough and uneven and beset with nodules and scars close to the pulmonary valves. Microscopical examination showed these nodules to be of gummatous character. The pulmonary valves were partially adherent to these growths, the mitral valves showed a slight degree of incompetency, while the tricuspid valves were thickened and fibrous. The pulmonary arterio-valvular condition was the most marked lesion present. Dr. Kasem-Beck points out the difficulty of diagnosing between such a pulmonary stenosis and mitral regurgitation, because if a diagnosis of pulmonary stenosis should be made on signs and symytoms such as those above given, it would in nine cases out of ten turn out to be incorrect and mitral regurgitation would be found to be present instead. The presence of a history of syphilis would, however, render a diagnosis of pulmonary arterial lesions relatively more likely.

REFORM IN THE BRITISH MEDICAL ASSOCIATION.

AS is well known to our readers a committee was appointed at the late annual meeting of the British Medical Association at Ipswich to "consider and report upon the best means of re-organising the constitution of the British Medical Association, such committee to furnish a provisional report to the branches by Feb. 1st, 1901." This Constitution Committee, which consists of Dr. A. G. Bateman, Dr. R. C. Buist, Mr. H. T. Butlin, Professor J. W. Byers, Mr. James Cantlie, Mr. Andrew Clark, Dr. J. Ward Cousins, Dr. H. R. Crocker, Dr. Alfred Cox, Dr. C. G. Gooding, Dr. W. Gordon, Surgeon-General J. B. Hamilton, Mr. Victor Horsley, Dr. J. C. McVail, Dr. C. H. Milburn, Sir John W. Moore, Mr. C. G. D. Morier, Mr. Edmund Owen, Dr. A. Brown Ritchie, Dr. R. Saundby, Dr. J. Roberts Thomson, Mr. T. J. Verrall, Mr. J. S. Whitaker, and Dr. S. Woodcock, met on Tuesday, Oct. 23rd, in the council room of the British Medical Association, Strand. Mr. Edmund Owen was appointed chairman and Dr. R. Saundby (Birmingham) deputy-chairman. The committee spent a lengthened period in carefully considering preliminary details in reference to the scheme of re-organising the Association.

THE TREATMENT OF METACARPAL FRACTURES.

IN a recent number of the *New York Medical Journal* Dr. Carl Beck describes an ingenious method of treating metacarpal fractures. The use of the x rays has shown that these fractures are not so uncommon as was supposed. Previously they were often diagnosed as dislocations or contusions. As there is usually no displacement, the other metacarpal bones acting as splints, the results under any treatment are usually good. In cases of displacement the result may be different. When the displacement is dorsal it is easily recognised and after reduction the fragments can be kept in place by splints, but in lateral displacements the results may be unsatisfactory, considerable deformity and loss of function resulting. In patients who perform delicate work with the hands, such as musicians, watchmakers, cabinet-makers, &c., a badly united fracture may prove a serious hindrance. Reduction is easy, but skiagraphy shows that under the usual methods of treatment the displacement quickly recurs. Experiments made by Dr. Beck show that in a case of fracture of a metacarpal bone the fragments can be held in place by two rubber drainage-tubes lightly pressed into the adjoining interosseous spaces so that they partly fill them up. The tubes can be kept in position by strips of adhesive plaster. The whole is surrounded by a "moss splint," a material which, after being dipped in cold water, adapts itself to the contour of the hand like a plaster-of-Paris splint, over which it possesses the advantages of being absorbent and much lighter. In one case a young man sustained fracture of the fourth metacarpal bone on striking a blow. There was considerable lateral displacement Reposition was easy. The fractured area was surrounded by narrow pads which were supported by adhesive plaster, and a long palmar extension splint was applied. Two weeks later the fragments were found to have slipped away from one another. After filling up the third and fourth interosseous spaces with rubber drainage-tubes a skiagraph showed perfect apposition of the fragments. On removing the tubes the displacement recurred.

DRUNK OR DYING?

ANOTHER of those unfortunate errors in judgment associated with the death of the person most concerned was the subject of inquiry by the East London coroner, Mr. Wynne Baxter, on Oct. 18th. The error in this case was primarily that of a police-constable and the person who died was Mr. Alexander Thomas, a cork merchant. The widow of the deceased said that he left his home on Sept. 27th to go to Broadstairs on business. He was expected home on the same night but did not arrive. On Sept 28th she received a telegram asking her to meet him at Snow-hill station. She did so and noticed that he complained of his head and seemed dazed. He informed her that he had been locked up, charged with being drunk, and fined at Broadstairs. He himself said that he was not drunk but had been taken ill and had fallen down while running to catch a train. He was taken home, attended to by Mr. F. J. Oxley, and died on Oct 17th. A police-constable said that he saw the deceased staggering towards the railway-station at Broadstairs. He fell down three times and cut his head A cab was sent for to take the deceased to the railway, but he said that he was all right and knew where he was going A medical man was called who expressed the opinion that he was the worse for drink, so he was taken to the police station. According to the report in the *Evening Standard* of Oct 18th the coroner here said to the constable, "Did you know that his skull was fractured?" to which the constable answered "Yes" Deceased was locked up and a medical man saw him on the next morning A careful examination was made but no fracture was found. Blood was oozing from one ear and the medical man suggested that deceased should go to the hospital but he refused. He was charged before the magistrate and fined 5s. Mr. Frederick J. Oxley said that he saw the deceased for the first time on Oct. 1st He was very ill and witness diagnosed fracture of the skull. On Oct. 16th deceased became comatose and died on the 17th. A post mortem examination confirmed the diagnosis. Witness thought it was probable that the deceased had suffered from cerebral hæmorrhage previously to the fall, which would account for his staggering about Another almost exactly similar case formed the subject of inquiry before Mr. G P. Wyatt on Oct. 22nd except that the patient after having been locked up from 10 P.M. on Oct. 13th was sent to the infirmary about 6 A.M. on Oct. 14th, where he died on Oct. 16th. Now these are just the cases in which an accurate diagnosis is practically impossible to make off hand. As to the constable who is reported to have said that he knew the deceased to have had a fractured skull, he either did not understand the coroner's question or he had no idea of what a fractured skull was. Probably he thought it was the same thing as a cut head. The name of the medical man who saw deceased first is not mentioned, but he seems to have advised somewhat imprudently. We cannot too often repeat that a man who is seen to stagger, to fall down, and to cut his head, and who is picked up in a dazed condition, may be suffering from one or more of a variety of conditions. He may be simply under the influence of some drug—alcohol, opium, or chloral; he may be suffering from uræmic coma; or he may, as was probably the case in this instance, have a cerebral hæmorrhage. Finally, the drug-poisoning, the uræmic coma, and the cerebral hæmorrhage may co exist. All these conditions are antecedent to the fall and would make the man dazed whether he fell or not. Secondly, the fall may daze him from simple concussion; it may so seriously injure the base of the skull as to bring about a large effusion of blood; or it may have no effect at all. It is absolutely impossible to differentiate accurately between all these conditions without a most careful examination, and generally a decided opinion cannot be given except after the lapse of a few hours. Ignorant and blameable as the conduct of the police was we do not think that any treatment, however skilled, could have averted the fatal result, but none the less the carelessness was inexcusable.

A SEVERE CASE OF ALVEOLAR ABSCESS.

AN interesting case of extensive suppuration due to a tooth is recorded in the October issue of the *Journal of the British Dental Association* by Mr. Alfred Kendrick. The patient, a man, aged 22 years, was first seen in May, when he stated that a year previously the left mandibular first molar had been fractured during an attempt to remove it. When seen by Mr. Kendrick a serious condition existed. The left eye was completely closed, both eyelids being extremely swollen, and pus was escaping freely from a sinus in the lower orbital margin and from the upper eyelid. A large sloughy opening was present in the centre of the cheek and there were several sinuses along the border of the mandible. There were sinuses near the clavicle and a large one over the sternum. The pus had burrowed upwards alongside the ascending ramus into the temporal fossa, so that the whole temporal region was œdematous The tooth was removed, but as the patient did not show signs of recovering it was decided to open up the various sinuses. These were scraped and packed with iodoform gauze, the patient making a steady recovery. The case is interesting as an example of the extensive suppuration which may occur in connexion with teeth.

HYPERTROPHIC GONORRHŒAL OSTEO-PERIOSTITIS OF THE FEMUR.

AT the meeting of the Société Médicale des Hôpitaux of Paris on July 27th M. Edgard Hirtz described a case of this rare condition. A girl, aged 19 years, in the third month of gonorrhœal rheumatism showed a considerable swelling of the lower two-thirds of the right femur. The bone was more than double its normal volume. The consistence of the swelling was such that it suggested hyperostosis, but a skiagram showed that it contained very little bone and that the process was principally a hypertrophic periostitis. The swelling was quite indolent, had developed insidiously, and was noticed only by chance. At the same time arthritis of the right knee and leucorrhœa still persisted. Salicylate of soda and iodide of potassium were given without effect. M. Hirtz insisted on the rarity of this form of gonorrhœal hypertrophic periostitis of which the symptomatology and evolution were profoundly different from the gonorrhœal periostitis usually observed in the epiphyses and small bones of the hands and feet.

THE Harben Lectures of the Royal Institute of Public Health for 1900 will be given by Professor A. Calmette, M.D., Directeur de l'Institut Pasteur de Lille, on

THE WAR IN SOUTH AFRICA.

THE military situation is unchanged. Ex-President Kruger has left for Europe and marauding bands of Boers still hold the field.

It may be remembered that Mr. T. W. Edmunds, honorary secretary of the Durban Government hospitals, some time ago wrote a long and strongly condemnatory letter to a contemporary in which he charged a number of army medical officers with incompetency, and medical orderlies with brutality, and alleged a criminal lack of invalid accessories. He also stated that if the Commission were honestly desirous of getting at the truth evidence enough would be forthcoming to convince the most sceptical. It would hardly be believed that when called as a witness and confronted before the Royal Commission with these allegations he was unable to substantiate one of them, but such, according to the *Cape Argus* of Sept. 21st, was the fact. He had to confess that he had no personal knowledge and was going entirely on hearsay evidence. It is needless to add that he had to withdraw all he had said. Lord Justice Romer had not, however, done with him, but called his attention to the statement regarding the honest desire of the Commission to get at the truth. He withdrew this also. As the witness could give no information the President said there was no use in hearing unsubstantiated general statements.

In the report which we gave in our last issue (p. 1167) of the very interesting address of Professor Chiene, outlining his experiences as a consulting surgeon in South Africa, which he delivered in opening the winter session of the class in surgery in the University of Edinburgh, we notice among other things that he touched upon the subject of enteric fever and its causation. Speaking of what he had heard of the serious illness of comrades and friends attacked with this fever or suffering from dysentery Professor Chiene said: "Norval's Pont had been an important camping ground since Oct. 1st and was covered with dried enteric and dysenteric dejecta. Dust-storms drove the poison into every nook and cranny of tents and huts. From the very first every precaution had been taken, but it was no question of water or milk. It was one of dust and flies."

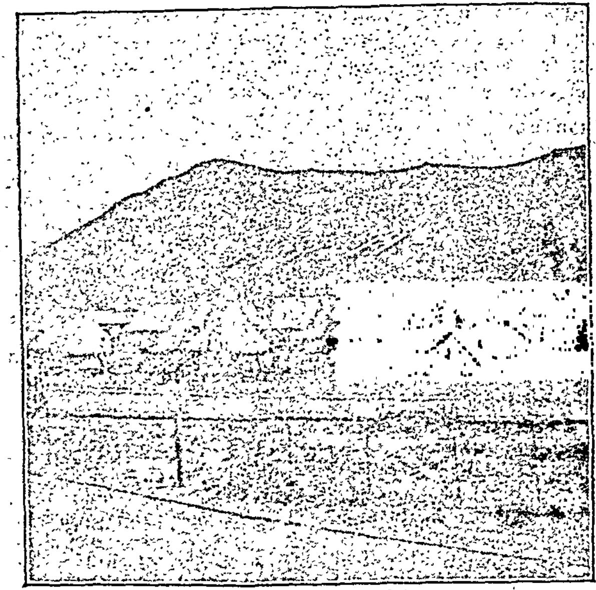
A TRIP FROM CAPE TOWN TO KROONSTADT.

(FROM OUR TRAVELLING CORRESPONDENT.)

I have just had a very pleasant and interesting trip in No. 5 Ambulance Train which enabled me to pay flying visits to all the larger military hospitals on the lines of communication between Cape Town and Kroonstadt—a distance of upwards of 800 miles. The train ran up to Kroonstadt with a large quantity of Red Cross, medical, and "Field Force Fund" stores for distribution at various stations, "loaded"—i.e., took on 96 sick and wounded—at Kroonstadt, and then ran back to Norval's Pont to unload.

Leaving Cape Town in the evening we reached Deelfontein, 30 miles south of de Aar, on the next afternoon. The train stopped here for nearly an hour, right in the middle of the Imperial Yeomanry Base Hospital, which at this point bestrides the line, the wards and administration huts being on the west side and the staff and convalescent annexe tents on the east. Colonel A. T. Sloggett, R.A.M.C., commandant, and Mr. H. A. Ballance, chief of the surgical staff, very kindly showed me over their magnificent hospital, of which they are justly proud. The Yeomanry Hospital has been so frequently described and lauded in the medical press that I need not weary your readers with a detailed description. It must be remembered that it is a *base* hospital, that it has not had to contend with the transport difficulties of hospitals farther up country, and that its treasury is always overflowing. There were 997 cases under treatment (this includes the convalescents in the bell-tent annexe) at the time of my visit. The serious cases occupy the wards (partly huts and partly tortoise tents) on the western side of the line, while the convalescents, the staff, and the orderlies live in bell-tents on the eastern side. Patients have not only every comfort, but every luxury imaginable and the administration of the hospital had been reduced to an exact science under the benevolent despotism of Colonel Sloggett, the tactful and popular commandant. Mr. Fripp has gone home and his place as surgeon-in-chief has been taken by Mr. Ballance. The site of the hospital—a narrow strip of ground under a high kopje—is not an ideal one, necessitating as it does crossing the railway main line to reach the convalescent and staff camps and cramping the huts and marquees rather closely together. The beds in some of the huts and tortoise tents appeared to me to be somewhat too near each other. Convalescent officers mess with the hospital staff. I think it is a pity that this practice has been adopted, as it is an objectionable one from many points of view; however, it seems ungracious to pick out slight defects in this splendid institution.

FIG. 1.



Imperial Yeomanry Hospital. General view of site at Deelfontein.

At De Aar and Naauwport I paid brief visits to the hospitals—No. 3 Stationary Hospital at De Aar, under Major J. W. Cockerill, R.A.M.C., 290 beds; and the section of No. 6 General Hospital at Naauwport, under Major Hassard, R.A.M.C., 150 beds. In both hospitals there were many vacant beds. I was very favourably impressed with the neatness, cleanliness, and general efficiency of both.

FIG. 2.

Edinburgh Hospital. Interior of a ward.

long halt. Here there is a large convalescent camp accommodating over 1000 men who all seemed very happy and comfortable. The camp is some distance from the station. Close to the station, with which it communicates by a special siding, is the pretty little Edinburgh Hospital, which by universal consent is believed to be the most perfect of its size in South Africa. Sir James Clark, commandant (since gone home), took me over the hospital and explained the entire system of working. Situated on an excellent dry site to the west of the line the hospital proper is composed of four long wooden single storey huts, raised from the ground so as to allow free passage of air beneath, and roofed with corrugated iron; the roofs are lined with white and the walls with green canvas. Each hut is divided into two wards of 20 beds each; between the wards are rooms for nurses and orderlies, and at the ends sculleries, urinals, and water-closets (dry earth system). The four huts are parallel with each other, the windows facing south-west and north-east. Verandahs were being built at the time of my visit and these will prove a distinct acquisition in the approaching hot weather. The interior of the wards is bright and cheerful to a degree; flowers, books, and papers strew the tables, and the walls are tastefully decorated with pictures. Each patient has a large bed-side table for his little belongings and lies on a comfortable "Abercrombie" bed. Space is more than ample and the hospital could easily take 20 more beds without overcrowding. Behind the wards is another large hut for the medical and nursing staff and dressers, with separate huts for kitchen, general, pack and medical stores, surgery, soda-water factory, and electric plant. The whole hospital is lighted by electricity. The latrines, a washhouse, and a disinfecting hut are situated well away from the hospital to the west. The water-supply, from a deep artesian well, is pure and practically inexhaustible. The hospital has its own electrical engineer who also manages the soda-water factory, its own resident builder, and a small corps of Kaffir ladies who do all the hospital washing. The operating theatre is somewhat small, and hot and cold water are not laid on; but as serious surgical operations are infrequent this defect is not a very important one. On the whole, the Edinburgh Hospital is practically perfect of its kind and Scotsmen may well be proud of their gift to the nation.

After a short halt at Springfontein, where I only had time to admire from a distance the mathematical precision of the lines of Colonel Duke's hospital (half No. 3 General Hospital), we reached Bloemfontein late at night, 50 hours after leaving Cape Town. Here I was informed that Professor J. L. Notter, Dr. Simpson, and Major Bruce, of the Enteric Fever Commission, had arrived and had commenced work. I have already in a former letter[1] given a fairly complete sketch of the Bloemfontein hospital arrangements. The Principal Medical Officer of the Army, Surgeon-General W. D. Wilson, has his headquarters here, but he hopes soon to transfer them to Pretoria. The Hospitals Commission left Bloemfontein for the north just as we arrived, in a magnificent special train adorned with huge red crosses. All who have attended the sittings of the Commission are agreed that so far the Royal Army Medical Corps has come out of the ordeal unscathed and that there is every ground for believing that the ultimate finding of the tribunal will convey an adequate recognition of the services of military and civilian surgeons out here.

Kroonstadt was reached late on the next night, exactly three days' journey from Cape Town. The hospitals here, No. 3 General Hospital and the Scottish Hospital, cannot be dismissed in a few words, and as my letter is already a lengthy one I propose dealing with them in a subsequent communication.

Kroonstadt, Sept. 19th.

"BIAS IN CLINICAL MEDICINE."

DR. JUDSON S. BURY of Manchester delivered an interesting address on the above subject on Oct. 17th, to the members of the Medical Society of University College, London, on the occasion of the society's annual public night held at University College. Dr. Bury said that as students and medical men one of their main duties was the examination of patients. His experience was that this was not always done in a satisfactory manner. There was need for more care; the examination was too often carried out in a perfunctory manner. For example, they found bronchitis and thought that that was a complete diagnosis, but they omitted to consider the aching pain through the left side of the chest which the patient had mentioned several times and which, as the necropsy showed, was due to an aneurysm of the descending portion of the aorta. The bias of bronchitis had entered the mind and its door was closed to the consideration of other symptoms. The customary use of the word "bias" was in accordance with its original meaning and a person was said to look at things in a biased manner or obliquely. The causes of bias were partly congenital and partly acquired. As an example of congenital bias Dr. Bury gave a description of a medical student afflicted with this peculiar mental blindness at work in the wards of a hospital. He appeared to have no idea how to proceed when asked to examine a patient whom he regarded as a strange foreign animal, and exhibited a distinct mental bias against approaching him too closely. When persuaded to go near the patient and prompted with certain questions to ask the patient he repeated the queries and although intelligent answers were given him they did not seem to afford his brain any guide as to the mode of procedure. Education might do something for this type of student, but the mental bias against scientific method was too strong for much success to be attained. By acquired bias was meant a condition that might affect the mind of good average development and promising scientific aptitude. One of the chief causes of this was imperfect education allowing the mental faculties to work in a fixed groove. Sir J. Russell Reynolds used to tell how once at the practical examination in medicine for the London M.D. he asked the candidates after they had examined one of the skin cases if they noticed anything else wrong with the patient and most of them failed to observe that one side of the face was completely paralysed. They were biased in favour of skin lesions and could not observe anything else, but if they had been told that it was a nervous case the facial paralysis would not have escaped their notice. The cure was to have a detailed methodical scheme and when anyone felt nonplussed over a case to be sure that all the headings of the scheme had been gone through. Another form of bias was the bias of authority, by which term was meant all statements with regard to disease and its terminology to be found in the best medical literature. It seemed paradoxical to affirm that the knowledge of disease already gained acted in some degree as a retarding agent, yet there was an element of truth in such a statement. A fresh discovery in medicine might turn the mind too much in one direction and destroy the comprehensive view necessary for real progress. All authoritative statements, even the names of diseases, might in a sense be regarded as productive of mental bias; the remedy was to strive to acquire a scientific habit of mind. If an original investigation was made into the classification of diseases into curable and incurable and observations were made with regard to the course and termination of morbid processes it was found less possible to draw sharp distinctions between curable and incurable diseases. In illustration of this Dr. Bury quoted a case of his own of a girl who exhibited definite objective signs of brain disease, which were observed and verified both in Manchester and in London. All the symptoms entirely passed away and the patient regained her sight and health and was able to resume her occupation. Such experiences tended to modify their views in two directions: they made them more careful in the treatment of ailments that tended to recovery and more hopeful regarding those which, as a rule, pursued a downward path. Proceeding further, Dr. Bury said that the bias of inclination was especially dangerous, and it came to the front in reports of cases and in essays and monographs on special diseases. The specialist, perhaps unconsciously, did not give full consideration to features which pointed to another conclusion—he regarded these as exceptional, and laid stress on facts which favoured what he wished to believe and ignored facts which told against his inclination. It was necessary to remember that having decided in favour of a particular diagnosis their mind must not be closed to the possibilities of future developments. The bias of specialism was another danger to be guarded against; a division of labour was necessary for the advancement of any science, but if energy was concentrated in a particular direction it

---

[1] THE LANCET, August 25th, 1900, p. 601.

[illegible] there. It was desirable, [illegible] rain his tendency towards [illegible] to curb his ardent desire to cut or scrape the throat of every child who was brought to him. The last bias which Dr. Bury described was the bias of physical signs. A patient was not an automatic machine into which a penny could be dropped to pull out a particular disease ready for treatment. On the contrary, the organs by which he moved and lived were composed of living tissues which had a past history and a future development, both of which required consideration before the case could be properly grappled with. The thoughtful qualified man [illegible] The man who got into a habit of regarding every patient as merely a "case" and who ignored the look of feebleness or of distress, or the expression of anguish, and thought only of physical examination, was not well equipped for the diagnosis of obscure disease—he became a machine which was totally unable to unravel the complicated problem of human pathology. Three things were essential for the preventive treatment of the disorder known as bias—namely, care, doubt, and truth, and if one thing helped more than another to avoid the pitfalls of bias and of hurried unscientific work it was that practitioners should put themselves in sympathy with their patients and that they should care for them in the way that Dr. James Jackson, the hero of Oliver Wendell Holmes, cared for his patients. Jackson would have it that to cure a patient was simply to care for him. Such devotion was only to be looked for in the man who gave himself wholly to medicine, the noblest of arts which the gods of ancient religions did not disdain to practise and to teach.

ASYLUM REPORTS.

Warneford Asylum, Oxford (*Annual Report for 1899*).—This institution, intended for the care and treatment of patients of both sexes belonging to the upper and middle classes of society, does not receive patients suffering from idiocy, epilepsy, or paralysis. The regular terms of admission are £2 2*s.* a week, but the committee of management have power to alter these terms at their discretion. The average number of patients resident during the year was 91, and comprised 42 males and 49 females. 15 cases were admitted in the year, nine being males and six females. Dr. James Neil, the medical superintendent, states in his report that one of the patients admitted had been a patient in the asylum on a previous occasion. 12 patients were discharged during the year, and of these eight—viz., four men and four women—were regarded as recovered, a proportion equivalent to 13·1 per cent. of the average number resident. The patients who recovered were in nearly every instance recent cases and none of them were admitted farther back than 1898. Two voluntary boarders were admitted suffering from a narcotic drug habit but have been restored to health. It is said to be doubtful, however, whether they may not relapse to their vice on exposure to temptation, "and the difficulty in treatment is to persuade them to submit to restraint long enough for the power of resistance to be established." There were five deaths during the year, a total of 5·5 per cent. of the average number resident, the respective causes being general paralysis, pachy-meningitis, pneumonia, organic brain disease, and senile decay. A large clerical element is present in the population of the asylum. Thus of a total of 108 patients under treatment during the year 30 were clergymen or the wives, widows, or children of clergymen. Regarding the tendency to overdo amusements, theatricals, &c., for patients Dr. Neil observes that while amusement is certainly an important means of brightening asylum life in some quarters at the present day it is overdone. "As a measure of treatment suitable and regulated work is more useful than amusement. For patients of the male sex there is no work equal to that afforded by a farm or garden....... Female occupation, such as needlework, has the disadvantage of being indoor employment and of requiring a sedentary and stooping attitude," but it is possible occasionally to persuade lady patients to do a little light work in the laundry. The committee of management state in their report that the financial position of the asylum is satisfactory and that improvements and alterations are made for rendering more agreeable the accommodation of patients. A reconstruction of the lava- [illegible] staircase for use in case of fire has been provided for the ladies' upper ward in the new building at the instance of [illegible]. The committee has been in [illegible] the purchase of about [illegible] Asylum. The increasing [illegible] has suggested to the committee the propriety of encouraging a special link between them and an asylum [illegible] with the Medical Sch [illegible] Commissioners in th [illegible] work is done in keeping private patients at the low rates current in this institution. "Many patients live here who, but for the advantages given by this hospital, would have to be cared for in a pauper asylum." The case-books are said to be [illegible] the care and [illegible]

W[illegible] (*Annual Report for 1899*).—The average number of patients resident during the year was 125 and comprised 52 males and 73 females. 28 cases were admitted during the year, 16 being males and 12 females. 25 of the 28 cases were first admissions. Dr. P. Maury Deas, the medical superintendent, states in his report that as regards the character of the cases admitted 18 could be regarded as affording more or less hope of recovery, while the remainder were hopeless from the first—five from the long duration of the malady, three from organic brain disease, and two from old age. In seven cases the bodily health and condition on admission were decidedly bad, while in 11 there was impaired health of various kinds. In 15 cases the chief cause of the mental trouble was considered to be conditions affecting the bodily health. Among other factors of causation three were due to overwork in young students, in nine the malady was due to anxiety, worry, and other emotional causes, and two were directly traceable to intemperance. In 11 cases heredity was traceable and in nine the contributing influence of former attacks existed. As regards the results of treatment, the number of patients discharged as recovered during the year amounted to seven (three males and four females), or 5·6 per cent. of the average number resident. The deaths numbered six (five being males and one female), or 4·8 per cent. of the average number resident, four resulting from melancholia, dementia, general paralysis, and epilepsy respectively and two from senile decay. About 12 patients have usually enjoyed the privilege of walking out unattended beyond the grounds "on parole." This privilege, which is a great help to treatment and a powerful encouragement to self-control, has seldom been abused by the recipients. A branch establishment in the form of a home at Dawlish forms a valuable adjunct to the means of treatment. "Some permanent cases find a quiet and comfortable home there, and many patients who go there for change or in convalescence appreciate greatly the more domestic and home-like life." The committee of management state in their report that £904 has been spent under the head of alterations and repairs of the institution. The weekly rate of payment per patient is £2 7*s.* and upwards, according to the nature and requirements of the case, and patients paying higher rates are allowed private rooms and special attendants.

Belfast District Asylum (*Annual Report for 1899*).—The average daily number of patients resident during the year was 922 and comprised 494 males and 428 females. The admissions during the year amounted to 334, the highest number since the opening of the asylum, the corresponding figures for the previous year being 281. Part of this increase is explained in the report by Dr. William Graham, the medical superintendent, as due to the growth in population of Belfast during the year, the facility of admission, and the transfer of a number of chronic mental cases from the union workhouse to the asylum. "These cases of chronic insanity," says Dr. Graham, "while giving perhaps but little hope of eventual recovery, show a steady improvement, a growing amelioration of their unhappy condition which, from a humanitarian standpoint, well repays the financial outlay....... They experience a greater amount of personal liberty, are engaged in healthful agricultural pursuits ..... and manifest a cheerfulness and interest in life previously unknown." Regarding the increase of the insane in the population of

Belfast, this is considered as slight and not sufficient to afford grounds for pessimism. Of the causes of insanity among the admissions the three to be most emphasised were hereditary influences, intemperance in drink, and bodily diseases. Dr. Graham says: "Here there seems to be room, without yielding to Utopian dreams, for the legislator to minimise the temptation to drunkenness. As to the third cause, so far as insanity is complicated by pure bodily disease, there is ground for hope. A considerable proportion of physical maladies contributing to the production of insanity are themselves the fruits of disobedience to physiological laws. ...... Much might be done by our educational systems to familiarise the minds of the young with the laws which regulate and preserve health. Even in the causes commonly described as moral, such as domestic troubles, to which 10 cases have been attributed, and religious excitement, which accounts for nine, there was evidence that behind these causes there was a reduced physical condition which made resistance to those emotional disturbances less possible." The number of cases discharged as recovered during the year amounted to 100, or 10·8 per cent of the average number resident. This slightly diminished recovery-rate is attributed to the increased influx of the chronic insane from the union already referred to. The deaths during the year amounted to 79—viz., 39 males and 40 females—or 8·6 per cent. of the average number resident. 20 post-mortem examinations were held. 16 patients died within one month of admission. The causes of death were as follows. One was due to suicide by strangulation, 13 were due to general paralysis of the insane, six to senile and general debility, 14 to mania and melancholia, 12 to phthisis, 14 to inflammation of the lungs and membranes, and three to epilepsy. Zymotic disease prevailed to a slight extent. In the beginning of the year one female patient succumbed to enteric fever. There were 11 cases of erysipelas, one of which proved fatal. Owing to legislative changes the old board of governors has been succeeded by a committee of management consisting of members of the local authority who have already displayed skill and public spirit and a grasp of administrative detail which, says Dr. Graham, augurs well for the future working of the institution.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Islington.—As usual, the annual report of Mr. Alfred Harris, the medical officer of health of this district, is a very complete one and deals in detail with the statistics relative to the parish. We can, however, touch upon a few points only. The density of population in Islington is no less than 112 persons per acre, as compared with 68·8 persons per acre for Bolton, the most densely populated of the great towns. Huddersfield has a density of population of but 8 7 persons per acre and Liverpool 47·9. Mr. Harris is fully alive to the fallacies which underlie these comparisons of density, but he thinks that even when all allowances were made Islington would still retain the lead as regards density. Moreover, the fact that the rate of increase of population in Islington is now very small lends additional support to the position taken up by Mr. Harris. The approaching census is matter for consideration by the author of the report before us, and he makes some good suggestions as regards the appointment and control of the enumerators which may well be noted by the Registrar-General. Under the heading of "Adulteration of Food" some useful information is supplied, and the control of the milk traffic in Islington is clearly an energetic one, the Sunday trade being by no means overlooked. Out of 532 samples of milk examined 181 were procured on Sundays and 231 on other days; the remaining 120 were procured in transit at the railway stations. Of the Sunday samples 14·9 per cent. were sophisticated. Of the week-day milks 11·6 per cent. were sophisticated. With these results it is useful to compare the samples which were taken at the railway stations, for out of the 120 samples examined only 0·8 per cent. were adulterated, a revelation which indicates that the dairyman is far more successful in controlling the farmer than the sanitary authority and the public are in controlling the milk-vendors. All the samples of milk taken in Islington were examined for boric acid, which was found in 26·7 per cent. Of the boracised milks 10·6 per cent. were adulterated, while of those not containing this preservative only 7·7 per cent. were adulterated. Boric acid was apparently the only preservative looked for. Of the 181 Sunday milks, 55 were preserved by boric acid, while of the 231 week-day samples 58 were thus preserved. Of 120 samples of railway milk 29 contained boric acid. The Islington vestry is to be congratulated on having set the example in London of examining milk for the tubercle bacillus. It was found that 14·4 per cent. of the milks examined were infected with tubercle and there was considerable suspicion in regard to another 14·4 per cent. Curiously enough, the samples of milk obtained from farms in the country were more infected with tubercle than those obtained from the urban cow-houses. Perhaps this means that the sanitary control of cow-sheds, &c., in towns is better than it is in the country.

Manchester.—In his last quarterly report on the health of Manchester Dr. J. Niven records the result of the administrative work relative to phthisis. He states that during the quarter ended June 30th 226 cases of phthisis were notified (voluntarily) by medical men in connexion with public institutions and 152 cases by medical practitioners in their private capacity. Out of this total of 378 cases the two medical men appointed by the corporation for the work visited 366, but in several instances repeated visits had to be made before the patients were found at home. Notification of advanced phthisis is not yet complete in Manchester, as there were during the period in question 147 deaths from this disease concerning which the sanitary authority were unaware. But in these cases disinfection was duly carried out. The notifications referred to have resulted in much good work in the direction of disinfection, no less than 181 houses having been thus dealt with. In addition to this 178 houses have been cleansed by the occupiers themselves. Under the provisions of the Manchester General Powers Act, 1899, 75 samples of milk taken at the Manchester railway stations have been subjected to bacteriological examination, and four of these were found to be infected with tubercle.

Warwickshire County District.—We welcome the advent of another genuine county report, this time that for Warwickshire, for although Dr. Bostock Hill has for the last 11 years summarised the local annual reports for this county the present is his first annual report as county medical officer of health. Slowly, but surely, the several counties are falling into line, and soon we shall hope to be able to think of a complete county health service. From the standpoint of population Warwickshire is not of great importance, its total of 352,935 being considerably less than those of several of the large towns. The birth-rate for 1899 was 27·98, there being but little difference between the urban and rural rates, while the general death-rate amounted to 15·93 per 1000. As regards the prevalence of zymotic disease there is nothing of general interest to record, but enteric fever was unduly prevalent in certain districts, and Dr. Hill used the occasion to insist upon better scavenging and the paving of courts and yards in thickly populated districts. The death-rate for diarrhœa was 1·14 per 1000, a rate which is in excess of those of all the other six principal zymotic diseases taken together. Dr. Hill points out the necessity for cleanliness of soil and air in the prevention of diarrhœa, and to this recommendation we should be inclined to add a better control of the milk-supply. The infantile mortality of the county was 142 per 1000 births, the rate for Aston Manor being no less than 194, and that for Nuneaton 166. The importance of popular education in the control of this terrible tax on infant life is dwelt upon by the county medical officer of health. Notification of infectious disease is now, of course, general throughout the county, and the great educational centre of Rugby has the honour of having held out against voluntary notification to the end. So, too, in the matter of isolation accommodation Rugby possesses no general infectious diseases hospital, but in connexion with the subject of isolation for the county Dr. Hill promises a further report. Vaccination is not going well in Warwickshire and the report before us advocates that pressure should be put upon the guardians by the sanitary authorities. Unfortunately, in the rural districts these two bodies are largely composed of the same individuals.

Cornwall County District.—The sanitary committee of this county, which had a population of 322,316 in 1891, has not much to say in its annual summary for 1899 as to the sanitary requirements of the districts under its care. The general death-rate was 16 08 per 1000 and the zymotic death-rate was 1·132 per 1000. The infantile mortality was 135 27 per 1000 births, as compared with a rate of 163 per 1000 births for England and Wales for the same period. As regards measles "the mortality-rate worked to two places of decimals is represented by zero." The diarrhœal death-rate was 0·48 per 1000, as against 0 98 for England and Wales. The enteric fever death-rate amounted to 0 14 per 1000. We should have been glad of some information relative to water-supply, sewage disposal, isolation accommodation, &c., in the county.

The Island of Guernsey.—Dr. John Brownlee, the newly- health of Guernsey, in his first annual tem of the registration of the causes of death by qualified practitioners in Guernsey and hence the records of the island in this sense are very defective. Dr. Brownlee has, however, been able to extract (*a*) the number of births and deaths for the last 20 years, (*b*) the ages of all who died between 1887 and 1898, and (*c*) the causes of death in so far as they relate to infectious diseases. It seems that this sanitary quickening in the case of Guernsey may be traced to the prevalence of diphtheria in recent years, an occurrence which led to the appointment of a special committee of inquiry which in turn recommended the appointment of a medical officer of health. Moreover, public lectures were arranged for, isolation accommodation of a sort was provided, and a laboratory was fitted up, and finally it was determined to form a board of health for the island Diphtheria has, therefore, not been without its uses in Guernsey. The total population of the island (including some 500 soldiers) is estimated at 37,905, and the general death-rate, corrected for age distribution, was for 1899 16·5 per 1000. The infantile mortality was 135 per 1000 births, as against a rate for the Isle of Wight (1881–1891) of 89 and for the Scilly Isles of 117. "Convulsions" figure altogether too prominently in the causes of infantile deaths, and there is obviously much room for improved certification. Infectious disease has in the past been but little under any control, but the medical officer of health will, we think, soon modify this condition of affairs. An improved water-supply seems to us one of the most pressing needs of the population We congratulate Guernsey upon its sanitary awakening

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6416 births and 3815 deaths were registered during the week ending Oct. 20th. The annual rate of mortality in these towns, which had declined from 18 4 to 17 1 per 1000 in the three preceding weeks, was again 17 1 last week. In London the rate was 15·8 per 1000, while it averaged 18 0 in the 32 provincial towns. The lowest death-rates in these towns were 10 4 in Halifax, 10 7 in Cardiff, 11·3 in Norwich, and 11·9 in Croydon; the highest rates were 22 3 in Manchester, 22·7 in Sheffield, 23 6 in Salford, and 28 6 in Gateshead. The 3815 deaths in these towns included 468 which were referred to the principal zymotic diseases, against numbers decreasing from 776 to 563 in the three preceding weeks; of these, 197 resulted from diarrhœa, 85 from diphtheria, 71 from "fever" (principally enteric), 43 from whooping-cough, 37 from measles, and 35 from scarlet fever. The lowest death-rates last week from these diseases occurred in Plymouth, Birkenhead, Bolton, and Halifax; and the highest rates in Swansea, Leicester, Salford, and Blackburn. The greatest mortality from measles occurred in Swansea; from scarlet fever in Sunderland; from whooping-cough in Gateshead; from "fever" in Portsmouth, Wolverhampton, Nottingham, and Preston; and from diarrhœa in Cardiff, Norwich, Blackburn, and Gateshead. The 85 deaths from diphtheria included 36 in London, nine in Leicester, eight in Leeds, and eight in Sheffield. No fatal case of small-pox was registered last week in any of the 33 towns; and only one small-pox patient was under treatment on Saturday last, Oct. 20th, in the Metropolitan Asylums hospitals. The number of scarlet fever patients in those hospitals and in the London Fever Hospital at the end of the week was 2342, against numbers increasing from 1703 to 2187 on the seven preceding Saturdays; 328 new cases were admitted during the week, against 318, 313, and 322 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 164 and 173 in the two preceding weeks, further rose last week to 182, but were 106 below the corrected average. The causes of 52, or 1 4 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Bradford, Leeds, Hull, Newcastle, and 12 other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Liverpool, Preston, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19 3 and 18·0 per 1000 in the two preceding weeks, further declined last week to 17·5, but showed an excess of 0 4 per 1000 over the mean death-rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 11·9 in Leith and 12 0 in Greenock to 18 9 in Glasgow and 23 0 in Aberdeen. The 542 deaths in these towns included 30 which were referred to diarrhœa, 14 to whooping cough, eight to diphtheria, six to "fever," five to scarlet fever, two to small-pox, and two to measles. In all, 67 deaths resulted from these principal zymotic diseases, against 107 and 74 in the two preceding weeks. These 67 deaths were equal to an annual rate of 2·2 per 1000, being 0·1 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had been 53 and 36 in the two preceding weeks, further declined last week to 30, of which 12 occurred in Glasgow, eight in Dundee, five in Edinburgh, and four in Aberdeen. The deaths from whooping-cough, which had been 18 and 13 in the two preceding weeks, rose again to 14 last week, and included seven in Glasgow and four in Greenock The fatal cases of diphtheria, which had been five and seven in the two preceding weeks, further rose last week to eight, of which five were registered in Glasgow and two in Edinburgh. The deaths referred to different forms of "fever," which had been 13 and five in the two preceding weeks, rose again to six last week, and included five in Glasgow. The fatal cases of scarlet fever, which had been seven in each of the two preceding weeks, declined last week to five, of which three occurred in Glasgow, where the two deaths from small-pox were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 98 and 104 in the two preceding weeks, further rose last week to 117, and showed an excess of 33 over the number in the corresponding period of last year. The causes of 18, or more than 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·0 and 26·4 per 1000 in the two preceding weeks, declined again to 24·9 during the week ending Oct. 20th. During the past four weeks the death-rate in the city has averaged 25 5 per 1000, the rate during the same period being 15 8 in London and 16 8 in Edinburgh. The 167 deaths belonging to Dublin registered during the week under notice showed a decline of 10 from the number in the preceding week, and included 19 which were referred t 36 and 21 in the two from diarrhœa, five and two from whooping cough. These 19 deaths were equal to an annual rate of 2 8 per 1000, the zymotic death-rate during the same period being 1·7 in London and 1·5 in Edinburgh. The fatal cases of diarrhœa, which had been 36 and 21 in the two preceding weeks, further declined last week to 19. The deaths referred to different forms of "fever," which had been three and four in the two preceding weeks, further rose to five last week. The three deaths from diphtheria showed a marked increase over the numbers in recent weeks The 167 deaths in Dublin last week included 36 of infants under one year of age and 32 of persons aged upwards of 60 years; the deaths both of to Mr. Owen's opinion my own experience has proved to me that in certain favourable cases when the surgeon has sufficient knowledge of mechanical therapeutic measures the patient need not be wholly confined to bed for any long period at all, but in every case when the symptoms point to activity on the part of the disease the patient should at once be put to bed or on a prone couch. For this reason it seems to me hardly proper to speak of "the modern ambulatory treatment of caries of the spine." I have notes of many cases of caries of the spine in which I have employed Chance's splint as an element in treatment. My own opinion is that the results thus obtained compare most favourably with those I have seen in cases treated by the instruments and methods that Mr. Owen advocates.

I am, Sirs, yours faithfully,
J. JACKSON CLARKE.

Old Cavendish-street, W., Oct. 13th, 1900

"THE VALUE OF ANTI-STREPTOCOCCIC SERUM."

To the Editors of THE LANCET.

SIRS,—Anti-streptococcic serum is only supposed to be of use in streptococcic infection—that is, in cases where the streptococci have actually got into the circulation. The two cases recorded by Dr. G. S. Walton in THE LANCET of Oct. 20th, p. 1132, are undoubtedly cases of sapræmia, or septic intoxication. With reference to the first case there is no mention of local treatment for the "putrid" lochia, which were apparently the cause of the trouble. I certainly consider that proper and efficient douching would have been more efficacious in this case, and would probably have saved the patient the trouble of a relapse. I am at a loss to understand why Dr. Walton attributes the cure of this case to the anti-streptococcic serum, as large numbers of similar cases recover without any treatment whatsoever.

I am, Sirs, yours faithfully,
Newcastle-on-Tyne. R. P. RANKEN LYLE.

THE BATTLE OF THE CLUBS: A SUCCESSFUL PRECEDENT.

To the Editors of THE LANCET.

SIRS,—The fifth annual meeting of the Eastbourne Provident Medical Association was recently held, and the report read showed that the association was in a healthy and well-established condition. There are 10 medical men on our acting staff and we have a membership of nearly 4000 persons. The gross income for the year ending August 31st, 1900, was £1071 9*s*. 9*d*. Our working expenses have been reduced to 15 per cent. and the remainder goes directly to the members of the acting staff. During the year we have adopted the plan of employing only one collector instead of two; and this has proved successful, as the work is now done not only more cheaply but also more efficiently.

I am, Sirs, yours faithfully,
A. HARPER,
Honorary Secretary, Eastbourne Provident Medical Association.
Eastbourne, Oct 23rd, 1900

"THE NOTIFICATION OF PLAGUE."

To the Editors of THE LANCET.

SIRS,—I should like to be allowed to make a few remarks upon the annotation in THE LANCET of Oct. 20th (p 1148), commenting upon the letters of Dr. Thomas Colvin and Sir William T. Gairdner, in which they deal with an apparent weakness in the Notification Acts. This weakness is not, I think, so great as might at first sight appear, and hardly calls for modification of the Acts as suggested by Sir William Gairdner. The certificate which is usually given by practitioners states, "I hereby certify that in my opinion such a person is suffering from a certain disease." But in actual practice a medical officer of health treats with the greatest respect a certificate upon which a query is placed after the name of the disease, and if given in good faith would certainly pass such a certificate through for payment by his authority, even though the subsequent history of the case proved the suspicion of the nature of the ailment to have been unfounded. Most assuredly would this be so with such grave diseases as plague or small-pox. Indeed, we always say that we would rather have half a dozen cases of chicken-pox notified as small-pox than miss the very earliest information of the occurrence of a single case of small-pox. It is well known that in most of our large towns an opportunity is afforded to medical men of verifying suspicious cases of diphtheria. Material is submitted for bacterioscopic examination and if no bacilli are found the practitioner in attendance is asked if he is still of opinion that he is dealing with a case of diphtheria If he replies in the affirmative the usual steps as to isolation, &c., are taken and the case is recorded as one of diphtheria; if he replies in the negative no action is taken with regard to the notification; but in either instance he receives payment for the certificate, and it would be manifestly unfair to adopt any other course. I cannot recall ever having received a certificate not given in good faith, and I can hardly think that my experience is unusual It is not by any means limited, for nearly 3000 certificates were addressed to me last year, and I fear this year I shall receive almost as many.

I am, Sirs, yours faithfully,
HERBERT JONES,
Oct. 22nd, 1900. Medical Officer of Health, Rhondda, South Wales.

"THE SMOKE NUISANCE."

To the Editors of THE LANCET.

SIRS,—The letter under the above heading in THE LANCET of Oct. 13th (p. 1098) does not refer to Section 21 of the Public Health (London) Act, according to which the vestry is compelled, on receipt of a memorial signed by 10 inhabitants, to take proceedings against the factory creating the nuisance. According to my experience, however, I find that the clerk of the vestry does not always take notice of such memorials, even when his own medical officer of health sympathises with the memorialists. Of course you can take out a mandamus, but is it not rather a remarkable thing that the inhabitants of a parish should be put to great expense through litigation in order to compel their own vestry clerk to do his duty?

I am, Sirs, yours faithfully,
Oct. 22nd, 1900. L. R.

⁂ The preventable damage to life and property from foul smoke is now recognised by the press and the public alike as being enormous. In the case of any vestry clerk acting in this way a statement of the circumstances properly vouched for should at once be sent to the press, when reform will follow.—ED. L.

THE ROYAL ARMY MEDICAL CORPS: "THE REASON WHY."

To the Editors of THE LANCET.

SIRS,—May I ask "the reason why" in the following queries with reference to the Royal Army Medical Corps?

1. Why is the "Passing-out" Examination at the Army Medical School, Netley, carried out solely by the professors of that school who are themselves the teachers of the school and not by independent examiners?

2. Why do Lieutenants R.A.M.C. become Captains R.A.M.C. without any test whatever of their knowledge of the special duties of their corps, while all other army lieutenants have to pass special tests for their captaincies? A "deadly seniority" alone ensures promotion to the captain's grade in the R.A.M.C.

3. Why is the technical examination for promotion to Majors of Captains R.A.M.C. in purely Royal Army Medical Corps military and administrative duties so unthorough, so narrow in its scope that it forms, so far as knowledge of the military and administrative duties of the Royal Army Medical Corps are concerned, a perfectly valueless test from its shallowness and superficialness? It generally consists simply of five or six written questions of babylike simplicity such as any Staff Sergeant R A.M.C. could assuredly pass.

4. What is a Lieutenant-Colonel R.A.M.C.? He passes no examination test, writes no thesis, and produces no plan of medical field duties whatever, although his combatant brother has to undergo a special examination for tactical fitness for command before promotion. Surely an officer of the medical service should not by mere monotonous and deadly seniority, without any efficiency test whatever, reach this essentially important post? Here, again, the merest seniority ensures promotion.

5. I also desire to ask, Why is there no "*staff examination*" which officers should pass for administrative appointments, such as secretaries, and for the higher posts of the brigade-surgeon's class of lieutenant-colonels and colonels? Such a test the late Sir Thomas Crawford instituted in 1884, but being apparently without clear convictions of its high importance he bartered away this essential and valuable check for a mess of pottage by allowing officers to pass for third-rate Fellowships of third-rate and impecunious colleges and so broke down a fence, or protection, or check against unfit persons rising into those important posts. A staff examination should be at once established.

6. Last, but perhaps of more importance than any other point, why is there not a well-paid Professor of Military Medical History and Administration at the Army Medical School at Netley to teach the young medical officers the important history of the work of the medical service in all our past wars, to tell them of the experiences of the old wars in Spain and on the continent, but more than anything else to explain the most instructive history of the Crimean War, from which terrible experiences date all our efforts to develop an efficient English medical service. Campaign after campaign comes round with its wretched story of medical undermanning and shortcomings, and yet each identical difficulty arose during the Crimean War, and its bitter story is told in the volumes of history and of blue-books published on that war. These reports in our blue-books need to be summarised and published, and the officers of the Royal Army Medical Corps who aim at administrative and staff employ should surely know what these sad records say. How few of the officers of the Royal Army Medical Corps have read or really know these deplorably sad histories. It is by thus studying the past that we can guard against breakdown in the future and by efficient examinations we can guard against the "deadly seniority" which in several of the R A M.C ranks absolutely ensures promotion. The State, which provides courses of instruction without number for engineer, artillery, and other military officers, does literally nothing in the way of post-graduate classes for the medical officers. Not only are these officers almost continually on foreign service, but when in England the advantages of special instruction, garrison classes on technical subjects, and post-graduate courses are denied them. How can a highly technical corps keep abreast of its work under such wretched conditions? A far more sympathetic treatment of the military medical service is needed, and we seem to look in vain for a war minister like the really great Sydney Herbert to grasp the needs of the corps and remove its many grievances. If only such a man would again appear in England what a blessing it would be!

I am, Sirs, yours faithfully,

Oct. 13th, 1900. "DEADLY SENIORITY."

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Extraordinary Rainfall in [illegible] —Further Increase of P[illegible] and Poona.—Decline [illegible] Bengal.

THE rainfall in Calcutta on Sept. 19th, 20th, and 21st was unprecedented. It flooded the city, caused great destruction of property, and rendered thousands temporarily homeless. It has since been followed by a great rise in the general mortality. The record registered is as follows:—Sept 19th, 14 35 inches; Sept 20th, 10 3 inches; Sept 21st, 8 58 inches. It will thus be seen that over 24 inches of rain fell during the first 48 hours. The rainfall during the week was nearly 45 inches. 12 people were killed, 17 were injured, and 182 brick houses and 409 huts fell to pieces. During the three days succeeding the floods the mortality has more than doubled itself. This has occurred almost entirely in the eastern and southern portions of the municipal area, especially in the latter. The chief causes of death have been cholera and diarrhœa. The filtered water-supply of the city has been rendered slightly turbid, but chemical and biological examination reports that it has not become contaminated. Every pond and surface well (from both of which sources of water the native prefers to draw) has had washed into it all the surrounding accumulations of filth. There is little wonder at the increase of mortality, more especially when so many thousands have suffered from exposure.

With this disaster in Calcutta there has during the past week been a further considerable increase in plague mortality throughout India and a continuance of the cholera outbreaks in the Punjaub and in Kashmir. Up to Sept. 23rd there have been in various districts of Kashmir 3416 cases and 1578 deaths, while in the Punjaub there have been 23,158 deaths and 42,805 cases of cholera. The plague mortality throughout India has risen from 1136 to 1442, the increase being chiefly in the Bombay province, especially in the Bombay districts and in Poona city. In Calcutta deaths from plague continue about the same, but in Bombay city the mortality from plague seems distinctly to be on the increase (95 deaths and a death-rate of 67 4 per 1000). The disease has rapidly advanced in Poona, where about 50 deaths from plague are occurring daily. In Mysore it is raging severely and the mortality continues to rise. There are apprehensions that a recrudescence of plague has occurred in Patna. Several deaths have occurred and rats are reported to be dying in considerable numbers. The popularity of inoculation for plague fluctuates enormously. While it has sunk almost to nothing in Bombay city it has been performed in nearly 5000 cases in Poona during the present month. There has been nothing done in this way in Calcutta for a long time, but in the Punjaub inoculation has met with favour.

The latest famine returns continue satisfactory, as the numbers under relief are now only a little over 3,000,000. 1,000,000 are still employed on relief works, and the remainder are receiving gratuitous relief. The famine in the Native States, according to official returns, has almost subsided. The Central Provinces are still severely affected.

The returns of vaccination in Bengal for the past year have recently been issued. In the towns the Compulsory Act is in force and an estimated number of 443 per 1000 children born have been successfully vaccinated. In the rural districts the number vaccinated is much less, reducing the proportion for the whole province to probably not more than one in five. This is calculating the birth rate at 50 per 1000. As it is, no less than 2,252 521 vaccinations were performed during the year.

Referring once more to the floods in Calcutta it will be interesting to note what effect, if any, these inundations will have on the course of another outbreak of plague. A very large proportion of the *busties* of Calcutta have during the past few months been disinfected, and the floors of the huts have been soaked with solution of perchloride of mercury. The recent floods have extended throughout many of these *busties* and have swamped the floors in thousands of the dwellings. Cattle and poultry have been drowned, and it is probable that the continuous immersion for three or four days of these hut floors may have affected the rat population. It will be remembered that the first epidemic in Bombay, which commenced (officially) in September, 1896, was preceded by an excessive fall of rain during the monsoon of that year. In the opinion of many dampness of site favours the spread of plague. If this be correct Calcutta may anticipate a still more severe outbreak than it has hitherto experienced. On the other hand, at least three dry months are in hand before the period returns when a recrudescence may be expected. The monsoon rains have probably ceased.

Sept. 27th.

SUCCESSFUL APPEAL.—We heartily congratulate Dr. F. E Paton, J P on the result of his appeal at the Monmouthshire Quarter Sessions on Oct 17th against a conviction registered against him at the Abergavenny Petty Sessions. The offence charged was being disorderly in a public place at Abergavenny in September. The appeal was allowed with costs.

SUPERANNUATION ALLOWANCE.—At the meeting of the Plymouth (Devon) Board of Guardians held on Oct. 19th it was mentioned that the superannuation allowance due to Mr. R Ellery, who had been medical officer of No 1 District for 30 years, was £48 10*s*. per annum, but as the board had power to add five or 10 years to this it was stated that at the next meeting it would be proposed that Mr. Ellery should be granted £50 per annum.

THE UNIVERSAL EXHIBITION OF PARIS.

(From our Special Correspondent.)

The Foreign and British Sanitary Sections.

At the western extremity of the great gallery of machines, which contains no machines but is devoted to the food products of the world, a majestic flight of stairs leads to an upper gallery where the sanitary exhibits of several nations stand side by side. Below, on the ground floor, in the Swiss food section, hedged round by Swiss condensed milk, and such objects, there are two large exhibits of Swiss sanitary school furniture. Why these were not placed with similar furniture in the Swiss education section instead of being in the food department, it is difficult to say. However, when found they are worth noting. The school desks are fixed to a moveable iron frame-work. Each desk may be used as a flat table or be either slightly raised on one side for writing or placed at a higher inclination for reading. It may also be lifted like the lid of a box. It then stands vertically in front of the pupil who faces the underneath part of the table or desk, and this serves as a "black board" which, however, is painted a dark brown as this colour is thought to be more restful for the eyes. Each pupil is thus provided with a large surface on which he can write or draw with a piece of chalk. It is pointed out that when anything is drawn or written on a large scale its shape and meaning are more readily understood by little children, and, further, that drawing or writing with chalk helps to develop skill of hand. Nor is this all, for the entire desk may be raised so high that the child must stand up to write upon it. Therefore the pupil may alternately stand or sit, and rest himself by this change of posture. Underneath there is a shelf for his books. A desk of this description with a seat for two in bench form and a rest for the back, all included, costs £2. This, then, would amount to £1 per child which does not seem dear considering the variety of advantages provided. This is the desk officially adopted for the Canton of Geneva and is manufactured by M. A. Maughain.

The German Empire Sanitary Exhibits.

Ascending the steps to the gallery immediately on the left of the landing is the German sanitary section organised by Dr. Koehler, President of the Kaiserliches Gesundheitsamt, and it purports to give some idea of the sanitary works accomplished in the German Empire. This sanitary authority, the Gesundheitsamt, assists the Chancellorship of the Empire in all that relates to the medical and veterinary police, in the application of sanitary laws, and in the elaboration of new measures. It not only seeks to protect the health of human beings and of animals, however, but it also endeavours to save vegteable life. This administration occupies 5558 hectares of land to the north-west of Berlin and near to the Thiergarten, where there are a large library, laboratories of all descriptions, offices and botanical gardens for experiments with plants, a disinfecting establishment, and stables for horses and other animals. The voluminous reports of the work done here are exhibited and they contain a vast store of learning and records of important experiments and investigations. For the last 24 years the drawing up of medical statistics has been studiously pursued. Statistics from 300 towns with an aggregate of 15,000 000 inhabitants are now regularly received and compiled. Little statuettes representing the Eiffel Tower show by their increase in size the growth of the population. Thus in the two great towns of the Empire in 1816 there lived 344,000 persons, in the six great towns in 1855 there lived 1,122,209 persons, and in the 28 great towns of the Empire in 1895 there were 7,276,987 inhabitants. Then whereas 84 years ago only 14 out of 1000 Germans lived in large towns, five years ago the proportion was 139 per 1000. But such statistics are for the most part to be found with the Pasteur exhibits on the Quai d'Orsay. Here, in the Machine Gallery, is shown some of the public works bearing on public health, such as the construction of hospitals and asylums, the new model slaughter-house of Cologne, drainage-works, &c. Then there are large models of the sanatorium of Hohenhonnel on the Rhine. The mountains, the woods, the beautiful surrounding scenery of the Rhineland are shown, so that the excellence of the site occupied may be fully appreciated. The sanatorium of Oderberg, in the Harz, is less attractive, for it dominates bare common-land but is sheltered to the north-west by a thick pine-wood forest, represented very prettily by little toy trees. The vast lunatic asylum of Zschadruss, in Saxony, seems more like a wealthy suburb consisting of mansions and villas surrounded by large pleasure gardens. A small model of the operating-room of the Nuremberg Model Hospital shows the double glass roof and the distribution in all directions of water and of heat. Similar toy-like models indicate the construction of the wards, &c. As this hospital was built so recently as in 1897 it may well possess many modern improvements, and the warming, the orientation, &c., seem to have been very carefully devised.

In another compartment there is a working model of an apparatus for cleaning large filtering beds employed at Hamburg. This consists of a floater under which is suspended a concave scoop. A pivot and wire ropes placed on each side of the filter-bed enable the floater to be drawn slowly across the water and the scoop below lifts off the slimy deposit from the surface of the filtering sand. The scoop is about four feet long. The pivots are then moved four feet further on and the next portion of the filter is cleaned. Thus, the clogging of the filtering beds is easily prevented and the sand is not disturbed by men walking over it to clean it. The operation, also, is more promptly accomplished and with much less labour. Of course, the town of Hamburg exhibits plans of its new water-supply and of its various sanitary institutions. The same can be said with regard to most of the other important towns of Germany. Indeed, we have here a collective and national exhibit of sanitation in the German empire. Nothing could be more important and more interesting, but, on the other hand, it is altogether beyond the scope of a brief description. To relate what each town exhibits would mean giving the sanitary history of all these great centres, and this would fill several volumes. The only thing that can be said in a brief notice is that this section is a museum of information. If, for instance, a person is especially interested in the treatment of sewage, in the construction of public slaughter-houses, or in sanatoria for tuberculous patients, or any other special subject of this description, he will see in the German section which are the towns in Germany where something special has been attempted in regard to one or more of these problems. He will also be able to ascertain what official and other reports have been published regarding the same, and he will then be in a position to know whether it is worth while going to those towns to investigate the question on the spot.

British Sanitation by State and Municipal Authority not Represented.

Undoubtedly in regard to sanitation it is the municipal and state sanitary authorities who should be the principal exhibitors. From this point of view the position of Great Britain by the side of Germany cannot be described otherwise than as most humiliating. There are some English manufacturers who are anxious to sell closet-pans and drain-pipes and they have very good exhibits, but of the great public works that have been accomplished throughout the country, and of which we have good reason to be proud, there is not the slightest trace. Well may it be said that we are but a nation of shopkeepers, for it is only the shopkeeping phase of sanitation that is to be seen at the Exhibition. Other nations strive to show what as nations they have been able to accomplish, and municipalities seek in a similar manner to distinguish themselves. But to judge from the British exhibits it would seem as if the British Parliament had never legislated for the preservation of public health, as if the municipalities had never provided public sewers or a public water-supply, and as if, in regard to sanitation, we could only boast of a few manufacturers who seek to sell closet apparatus, flush tanks, and drain-pipes on the continent, for there is no evidence that these things are required for use in England itself. There seems to have been no public enterprise. Those tradesmen who thought they might do some business by exhibiting their products sent specimens, but anyone visiting the Paris Exhibition to ascertain what progress had been made in sanitation in Great Britain would come away as ignorant as before. If any sort of indication is obtained leading to the belief that something has been done in England this will be found in a foreign, not in any English, section. Thus, for instance, in the German section there are mortality tables giving the average annual *death-rate per 100,000 inhabitants from small-pox* first for the years 1862 to 1876 then for the years 1882 to 1896. From this it will be seen that the mortality from small-pox has decreased in Prussia and Bavaria from 51·6 to 0·7, in Austria from 75·2 to 38·6, in Belgium from 79·5 to 18·2, in England from 25·6 to 2·9, and in Sweden from 26·9 to 0·5. Therefore in the German section and with the aid of German statistics an investigator would see that something must have been done in England at least in regard to small-pox, but he would find nothing in the British section to confirm this hopeful impression. Yet no nation could have made a more instructive and a more magnificent sanitary section than Great Britain if only someone in authority had taken the matter in hand. Messrs. Doulton and Co. and Mr. George Jennings have very fine exhibits, and, in their line these firms are pre-eminent throughout the world, but however excellent the sanitary apparatus which they manufacture they only represent the details of application. Millions of money have been spent in rendering both town and country more healthy, vast schemes have been carried out, the mortality has been reduced on all sides, and yet there is not at the Paris exhibition any record of this most creditable and beneficent work. It is easier to know what has been done in some pretty Italian town than what such centres as London, Birmingham, and Manchester have achieved. In such novel and important questions as the bacteriological treatment of sewage we have the careful record and maps and drawings of the experiments made in Germany, but there is no mention of the Exeter septic tank, of the Dibdin system, and of other similar trials made in England. This is undoubtedly a great omission and places British sanitary reformers in the shade by the side of their colleagues of the continent.

The United States.

The United States of America have managed matters a little better. With them, as with us, it is private enterprise that has shown the most activity and most of their exhibits are those of tradesmen anxious to sell or of private charities that are seeking to add to their list of subscribers and sympathisers. But still there are a few American exhibits that are of general interest. Thus, in the American section there is some account given of the isolation hospitals provided by various towns in the United States, accompanied with the modest assertion that not many towns have made this necessary provision for dealing with infectious diseases, but that their number is increasing. The Massachusetts Board of Health exhibits its documents, its official forms for the notification of disease, &c., and it is possible to get some idea of the sanitary laws and their application in that State. There are also some interesting charts that apply to the whole of the States. One of these is a map of the States in four colours. The darkest colour shows the States where no one [illegible] he has passed examina- [illegible] next colour gives the [illegible]e accepted and others rejected. [illegible] and comprise [illegible]ours, covering [illegible] first the States where any sort of diploma is accepted, and secondly, those states where no diploma at all is required. Another map shows the number of medical practitioners in the different States. A third map gives the expenditure per head during the year 1898 of the Board of Health. Very few States exceed two cents, many more vary from one to two cents, and for far the greatest number the taxation for sanitary purposes does not equal one cent. per head per annum, and there are actually some States where there is no tax, no public expenditure whatsoever for health purposes. Two more maps give the percentage of population supplied with public water in 1860 and again in 1897. In the former period public waterworks seem to have existed only in the north eastern States, but now there has been a great increase of waterworks throughout the country, though evidently much remains to be done. Finally there is yet another map which shows the percentage of persons who in the various States live in sewered towns. It is not necessary to point out that it would have redounded to the credit of Great Britain if similar maps, giving similar details, had been exhibited in the British Sanitary Section. By the side of the few public exhibits in the American section there is quite an army of private charities, hospitals, asylums, and homes, of societies for improving the condition of the poor, and of societies for the prevention of cruelty to children and to animals, &c. Some of these are strictly denominational. Thus we find a model of the Presbyterian Hospital of New York City and another of a children's hospital. There does not seem to be anything of any particular interest, technically speaking, in these exhibits; their object is rather that of exciting the charitable feelings and the generosity of visitors.

To the technician the large and varied exhibits of American stoves and warm[illegible] interest. In any case the [illegible] the gold medal. The air [illegible] this stove and can be delivered at a temperature of about 100° F., so that it is not burnt or super-heated. Then there is the New York Blower Co. which shows a fan for propelling warmed air into buildings. It is maintained that if revolving fans fit tightly in the drum in which they are placed they only churn up the air and do not send it forward and therefore a much shorter blade for the fans is employed. With regard to radiators and water and steam coils the Webster system professes to regulate the temperature so that the radiators shall not be too hot. In a word, there are many stoves and processes for warming and ventilation which profess to possess many virtues, and it should be possible to learn a good deal from the United States, for with the very lofty houses in America and the severity of the winter there the problem must present many difficulties. Still it would be somewhat hazardous to pronounce an opinion without making practical experiments. In regard to drainage there are but two firms exhibiting and one of these, the Standard Manufacturing Company, has its exhibits in the midst of the furniture on the Esplanade des Invalide, more than a mile away from the sanitary section. Though I went all this distance to see this exhibit all the attendant could tell me was that he had nothing new to show. Nor did I find anything particular that was new with a rival firm, the J. L. Mott Iron Works of New York, that exhibits a very beautiful bath-room in the sanitary section. The white enamel, the pale blue curtains, and the plentiful supply of electric light produced a charming effect and as a luxurious display it attracts the gaze of many visitors, and it has been awarded the gold medal.

Paris, Oct. 22nd.

LIVERPOOL.

(From our own Correspondent.)

Formal Opening of the Queen Victoria District Nurses' Central Home.

On Oct. 19th the Central Home of the Liverpool Queen Victoria District Nurses' Association, the munificent gift of the David Lewis Fund, in commemoration of the Queen's Diamond Jubilee, was opened by Mrs. William Rathbone in the regretted absence of her husband, Mr. William Rathbone the well-known Liverpool philanthropist. The nucleus of the buildings consisted of a large detached house which, partly by re arrangement and partly by the building of an additional wing, has bee[illegible] trative building. Mr. Ben[illegible] Fund, presided over a[illegible] the Lord Mayor and L[illegible] (the master of St. Katherine's), and others. No public charity has ever been administered with less ostentation than the David Lewis Fund, which has provided so many comforts for the benefit of the working-classes of Liverpool [illegible] At present there are at work on behalf of [illegible] of each, together [illegible] the cost of extra [illegible] would cost about [illegible]ubscribed by the [illegible] the association, [illegible] available for the extension of the work owing to various causes. The annual subscriptions so far have been about £300, the greater part of which had been contributed by a few individuals, so that if the work is to be successfully carried on a more extensive subscription list is absolutely necessary.

Generous Gift to the Royal Infirmary.

Mr. George H. Melly, a member of the committee of the

Royal Infirmary, has generously provided for the wards of the infirmary an electric installation at a cost of about £800.

Biennial Dinner of the Medical Faculty of University College, Liverpool.

The biennial dinner of the medical faculty of University College took place on Oct. 13th at the Exchange Station Hotel. The chair was occupied by Sir William Mitchell Banks. The guests included the Lord Bishop of Liverpool the Lord Mayor of Liverpool, Dr. Oliver Lodge, principal of Birmingham University, and 150 other gentlemen. The dinner was highly successful.

Proposed Isolation Hospital for Hoylake and West Kirby.

The Hoylake and West Kirby District Council have approved of a recommendation of the Health Committee to appoint a sub-committee to consider the proposed increased accommodation at the Wirral Joint Isolation Hospital and to report as to the advisability of the Council providing and maintaining an infectious diseases hospital for the district.

Thompson-Yates Laboratories' Reports, October, 1900.

The first part of the third volume of the Thompson-Yates Laboratories' Reports contains articles from Professor Rubert Boyce, Dr. Balfour Stewart, Dr. A. S. F. Grünbaum, Dr. J. H. Elliott, Dr E. W. Hope, and Miss Chick. Dr. Balfour Stewart, assistant bacteriologist to the Liverpool Corporation, contributes a most interesting article on "The Distribution of Bacillus Enteritidis Sporogenes." Miss Harriette Chick, 1851 Exhibition Scholar, treats of the "Distribution of Bacterium Coli Commune" in a very able manner. Professor Boyce's article upon the "Two Species of 'Fungus' commonly found in Sewage Contaminated Water" is well worthy of perusal. Dr. Hope's article exposes the inadequacy of the existing Food and Drugs Act. The volume is apparently a public health number and shows the amount of work which is being carried on in the pathological department of University College in the cause of public health under the able tutelage of Professor Boyce. It is pleasing to find the type increased in size, whilst the illustrations are exceptionally good. Volume III., like its predecessors, was issued from the University Press of Liverpool, and is edited as usual by Professor Boyce and Professor C. S. Sherrington, with the coöperation of the assistants in the departments of pathology and physiology.

Oct. 23rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

In Memory of Professor Rutherford.

A BEAUTIFUL stained-glass window has been placed in Ancrum parish church in memory of the late Professor Rutherford, professor of physiology for five years in King's College, London, and for 25 years in the University of Edinburgh.

Arthur Andrew Jamison, M.D. Glasg., M.R.C.P. Lond.

Dr. Arthur Andrew Jamison, who died on Oct. 17th at his residence, 18, Lowndes-street, Belgrave-square, S.W., at the age of 56 years, was educated at the University of Glasgow, where he graduated in medicine with honours and prizes in 1865. He was for a time assistant physician to the Dispensary for Skin Diseases, Glasgow. He was admitted a Member of the Royal College of Physicians of London in 1889.

Saturday, Oct. 27th, is fixed for the laying of the foundation stone of the Ochil Hills Sanatorium by Sir Thomas Glen Coats.

Oct. 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

THERE is a change in the representation of the Royal College of Surgeons in Ireland on the General Medical Council. Sir Philip Crampton Smyly has retired and Dr. Charles Bent Ball has been appointed in his place. Mr. J. S. McArdle has been elected a member of the Council of the College in the room of Sir William Stokes, deceased.

Royal College of Physicians of Ireland.

Sir Christopher J. Nixon has been elected to the position of President of the Royal College of Physicians of Ireland.

Housing of the Dublin Poor.

A meeting of the committee of the whole house of the Dublin Corporation took place on Oct. 22nd for the special purpose of dealing with the problems in connexion with the tenement houses and the dwellings of the very poor. A report, which was furnished by the town clerk after consultation with Sir Charles A. Cameron, expressed the opinion that the corporation could do very little more in the matter than they had already done unless they obtained by legislation power to borrow £500,000 for the purpose of clearing unhealthy areas and building dwellings for the working classes. Alderman Farrell, who filled the chair in the absence of the Lord Mayor, proposed that the corporation should proceed immediately to take steps to borrow £500,000 for the purpose of providing the required accommodation. A majority of the 40 members present were, however, of a different opinion in reference to hasty action in connexion with such an important financial matter and after discussion an amendment was carried to the effect that "the Public Health Committee be requested to prepare a return showing the area, population, and rateable valuation of the slums with a view to the preparation of a formal scheme and that the committee adjourn for a month."

Medical Men and Cricket.

On Oct. 16th, in Ye Olde Castle Restaurant, Belfast, Dr. J. W. Taylor, the captain and honorary secretary of the North of Ireland Cricket Club, was entertained by the members to a complimentary dinner to celebrate the great success of the club during the past season. About four years ago Dr. Taylor was appointed secretary of the North of Ireland Cricket Club, and by great efforts he has completely rescued it from its unsatisfactory condition, so that now it holds the premier position among cricket clubs in Ulster.

The Union Fever Hospital, Belfast.

The appointment of medical officer to the Belfast Union Fever Hospital, at a salary of £120 per annum, is to be made on Oct. 30th. It is generally thought that Dr. A. G. Robb will be appointed. The salary of the late occupant of the office was £165 per annum, but the guardians have reduced it, although the work remains exactly the same.

Health in Belfast Gaol.

At an inquest in the Belfast Gaol on Oct. 17th in reference to the death of a man from pulmonary hæmorrhage some very interesting facts came out in evidence as to the state of health of the prisoners there. The present coroner was appointed in 1893 and in that year there were no inquests, in 1894 there were two, in 1895 none, in 1896 one, in 1897 three, and in 1898 and 1899 none. It is, therefore, three and a half years since there was an inquest in the Belfast Gaol (March, 1897, was the latest occasion), and this notwithstanding the fact that the coroner by law must hold an inquest on every person who dies in prison. It speaks well that, while from 6000 to 7000 prisoners pass through the Belfast Gaol each year, there have been only six deaths in seven years. The medical officer of the gaol said that among the prisoners there was a considerable amount of bronchitis and pneumonia, but that they were entirely free from zymotic disease, notwithstanding that typhoid fever was very prevalent in the city and that the ordinary town water was used. He added that they had a good milk-supply, and that in summer, if there was any suspicion, they sterilised it. The food was good and wholesome and the prisoners were made to bathe every week. At present there was only one case of phthisis among the inmates. The coroner said that he hoped the Belfast Water Commissioners would take a note about the water. The jury found a verdict in accordance with the medical evidence, adding that every due and proper care of the deceased had been taken by the medical and other officials of the prison. The condition of the gaol and of the asylum in Belfast would certainly go to prove that in the causation of typhoid fever in that city the water cannot be a strong factor.

North of Ireland Branch of the British Medical Association.

On Oct 18th, at the opening of session 1900–1901 of the North of Ireland Branch of the British Medical Association

Association in Ireland, Professor Byers spoke of the great progress which the science of medicine had made in this century, instancing especially the new line of clinical and laboratory investigation of the new hæmopathology. Having given instances of the value of this method of specialised examination he then discussed very fully "the Present Position and Future Work of the British Medical Association." At the conclusion of the address a hearty vote of thanks was accorded to Professor Byers by the large meeting of members of the medical profession of Belfast and Ulster who were assembled in the museum. Papers on medical subjects by Dr. J. M. MacCormac and Mr. A. G. McKenna followed.

The Public Health Committee of Belfast.

At a meeting of the Public Health Committee held on Oct. 18th a deputation representing the Belfast and District Trades and Labour Council attended and urged upon the [illegible] for the adoption of a system of [illegible] of milk. They advocated the [illegible] mmended by Dr. Henry O'Neill [illegible] his report on this question but [illegible] at the corporation had not any [illegible] money out of the rates for providing or working an establishment for the sterilisation of milk or the sale of sterilised milk, and that no matter how useful such a department might be, it would be [illegible] obtain the sanction of Parliament [illegible] enditure upon it. Dr. O'Neill [illegible] the objection and he handed the chairman a bank deposit for £300 from two "grateful parents," whose child had been successfully treated by sterilised milk as recommended by Dr. O'Neill, and who wished the scheme recommended by him to be tested for 12 months. A sub-committee was appointed to consider the matter with the view of carrying into effect the wishes of the anonymous contributors.

The Health of Belfast in 1899.

Dr. Whitaker, medical superintendent officer of health of Belfast, has just issued his report for the year 1899. The deaths during this period were 7933; of these 1005 were from zymotic disease and 2865 from phthisis (1112) and diseases of the respiratory organs (1753). These together make a total of 3870, or nearly one half of those registered as having died from all causes. Of the eight principal zymotic diseases diarrhœa has occasioned the heaviest mortality (285) The number of deaths from enteric fever was 263, a material decrease from the preceding year; while the number of cases reported was 1598. The deaths from whooping-cough were 215 and from measles 146, neither of which are notifiable There were only 24 deaths due to scarlet fever, although 917 cases—a number largely in excess of the previous year—were notified. In fact, a mild epidemic of this fever has been prevalent throughout the year in Belfast. 61 deaths were due to diphtheria, 10 from simple fever, and only one from typhus fever. Turning to the mortality from phthisis it is really appalling to think, in spite of the recent crusade against tuberculosis, that there were 1112 deaths from this so called preventable disease during the past year, and, what makes matters worse, the mortality from this fell malady in Belfast seems to be increasing. Climatic influences, Dr. Whitaker tells us, have little effect on the death-rate from phthisis in Belfast, the deaths being as numerous in the warm as in the cold months. There is a branch of the Society for the Prevention of Consumption in Belfast. Surely with such a ghastly death-rate as exists in Belfast from this disease it has an abundant field to work in. Belfast has a population of 350,000 and when we read that of 7933 deaths which occurred during 1899, 1112 were due to phthisis alone, surely there must be some causes at [illegible] progress of sanitary reform and [illegible] years, demand the most careful [illegible] to infant mortality Belfast contrasts favourably with English manufacturing cities and towns, there being 160 deaths per 1000 births, as contrasted with 174 in Brighton, 191 in Birmingham, 206 in Manchester, and 255 in Preston The general death-rate in Belfast for 1899 was from all causes 22·7 per 1000 and 2·9 from zymotic diseases, as contrasted with 26 4 from all causes and 3 7 from zymotic [illegible] Belfast the birth rate for the year generally keeps pretty uniform. The death-rate from phthisis in Belfast in 1899 was 3 2, while it was 4·1 in Dublin City, 4·2 in Cork, 3 0 in Limerick, and 3 6 in Londonderry. The death-rate from diseases of the respiratory organs was 5 0 in Belfast, 6 9 in Dublin City, 4·5 in Cork, 3 7 in Limerick, and 5 0 in Londonderry. With reference to the mortality from enteric fever, while it is pleasing to note that it is less (263) than in 1898 (640), it is still greater than we have generally had in former years, and while in almost every other town or city in the kingdom the deaths from this cause have been steadily declining it is, unfortunately, not the case in Belfast. The disease seems not to be confined to any district of the city or to any particular kind of soil, and it is curious that "the dock district, as also Millfield and its neighbourhood, are the freest from this disease, although the former is low-lying, the houses are old, and sanitation is imperfect, and the latter district is one in which the houses are the oldest, the people generally of the poorer class, and lanes and alleys more frequent therein than in any other part of the city." Dr. Whitaker had 1370 houses in which the disease occurred carefully examined as regards their sanitary arrangements, and of these 898 had water-closets, while 472 had privies. As the houses with water-closets are four times as numerous as those with privies the proportion of houses in which typhoid fever occurred was: water-closets 1 in 63 as compared to 1 in 43 in privy houses. Dr. Whitaker again calls attention to the importance of an infectious diseases hospital and hopes that in his next report he may be able to indicate an advance towards the building of it. During the past year steady progress has been made in improving the sanitation of Belfast; it is to be hoped with Dr. Whitaker that the work of remedying the sanitary defects inherited from our predecessors will be pushed on by the Public Health Committee as rapidly as possible. Dr. Whitaker's most interesting report brings into prominence two very serious blots in the health of Belfast.. These are the terrible mortality from phthisis and the continued existence of enteric fever apparently as an endemic disease. Both of these maladies being now regarded as so largely preventable their very marked existence in Belfast is clear evidence that that city is in an unsatisfactory condition from a sanitary point of view. I use the term "sanitary" in a very wide sense as indicating that the Public Health Committee of that city must make renewed and really energetic efforts to remove all the causes which in any way predispose to the existence of two diseases—phthisis and enteric fever. In all great cities now these are the maladies in the stamping out of which sanitary science is gaining its greatest triumphs. We must not lag behind in this crusade in Belfast which though so large is such a modern city.

The North Charitable Infirmary, Cork.

At a meeting of the committee of the Cork North Charitable Infirmary Dr. Nathaniel J. Hobart tendered his resignation as senior surgeon. Dr. Hobart spoke with much emotion and referred to his long connexion with the hospital, extending over a period of about 40 years. During that time he was happy to say that his relations with his colleagues, with the board of management, and with all connected with the administration of the institution, had been most cordial. His only reason for resigning was because the advance of years was telling its tale and he thought it prudent to husband his strength. He thanked the governors for the very great courtesy which they had always extended to him, and he assured them that he would never cease to take a deep interest in the infirmary with which he had been so long identified. There is no doubt that Dr. Hobart's resignation marks an era in the life-history of the North Infirmary. An able diagnostician and a brilliant operator Dr. Hobart did much to maintain and improve the status of the infirmary as a clinical school His genial disposition and his *bonhomie* endeared him to more than one generation of students who are now scattered all over the globe as practitioners of medicine and who look back to the many happy days when he was their guide, philosopher, and friend He took a keen interest in the battle of the clubs at Cork and his matured experience and prudent counsel were always at the disposal of his colleagues. The public of Cork will join with the committee of the

the hospital, but also many severe and hopeless cases have to be admitted. The cases are thus on an average rather severer than those treated in private practice. Tracheotomy was performed in 96 cases, which corresponds to a percentage of 28·4. The mortality only reached 10·5 per cent of all the cases and 18·75 per cent. of the cases for which tracheotomy was performed. Albuminuria was present in 57 8 per cent. of the cases and could not be attributed to the serum injections as it was observed before the injections were given. Only in very rare cases of severe nephritis could diphtheria bacilli be demonstrated in the kidney after the post-mortem examination. The albuminuria proved to be in direct connexion with the extension and persistence of the diphtheritic membranes. Cases with gangrenous membranes proved especially severe, and all these cases, 24 in number, had albuminuria. Six of these cases (20 per cent.) succumbed to the disease. Four cases complicated by otitis media, three by severe sepsis, and 24 by paralysis of the pharynx all had albuminuria and all had been injected two or more days after the commencement of the illness. Of the tracheotomy cases 82 per cent. had albuminuria. Albuminuria is thus of the greatest value as a prognostic in determining the severity of the disease.

Zurich, Oct. 22nd.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Observations by Professor Grassi on the Habits of the Anopheles.

ANYTHING from the pen of Professor Grassi relating to malaria will be read with interest. He has just published another note in the *Rendiconti della R. Accademia dei Lincei*, describing some observations made by him in September of last year and during the past summer at Grosseto with the object of controlling the results obtained last year in July and August by Koch's expedition. The latter, it may be remembered, found very few anopheletes but a very great number of culices in this city, although malaria was very prevalent, and from this fact he considered it likely that culex pipiens is also an agent in the propagation of malaria. Professor Grassi, on the contrary, has found anopheletes very abundant in the same houses where Koch had noted malaria the previous year, and he concludes from this that Koch's party were inexpert at the work of looking for mosquitoes and that their search was not made in the proper places, which are the entrances of houses and outhouses and not in the bedrooms. He found that the favourite time for the anopheles to feed at Grosseto was the 30 or 40 minutes immediately after sunset and, to a much less extent, the same time before sunrise. They take long flights in search of food and like to go away shortly after feeding, for which reason they may be said to change every 24 hours, at least during the warm weather, only very few (about 1 per cent.) being consequently found infected in the height of summer. As the weather becomes colder they remain longer and a larger proportion (about 8 per cent) are found infected. The infected insects are apt to be conveyed passively over long distances and so spread infection to fresh localities hitherto exempt. Anopheletes are found in some places where no malaria exists as, e g., along the Lake of Como. Their larvæ live freely in salt water, and seaside places, though usually exempt, are not invariably so. Professor Grassi, in conclusion, confirms the observations of Christophers and Stephens on the occasional presence in the salivary glands of the culex of bodies which resemble, but which he does not believe to be, sporozoites. He calls them pseudo-sporozoites.

The Protective Experiments against Malaria in the Agro Romano.

In a former letter[1] some account was given of the measures that were being taken to protect from mosquitoes the employés along certain sections of railway, as well as those in the service of the Acqua Marcia and of the electric traction companies in the Agro Romano. The houses and huts of Cervelletta and Castella were also protected, the means used being similar to those adopted by Professor Grassi in his remarkable Albanella experiment.[2] Professor Celli, who has had the supervision of the experiments, informs me that the results have exceeded expectation, all the inhabitants of the houses and huts having remained quite immune from fever while those in neighbouring houses, purposely left unprotected for the sake of comparison, were all attacked by malaria. Of the 183 railway employés who were subjected to the test only five contracted the fever, and in all of these the attacks were traceable to neglect of the simple precautions recommended. The results thus obtained have proved so encouraging to the railway companies and other employers of labour in the Agro Romano that it is proposed greatly to extend the field of operations next malaria season, employing the same system of protection by means of wire gauze. The Society for the Study of Malaria intend to bring the matter before Parliament with the object of obtaining State assistance for dealing with the disease by the methods which these recent researches have shown to be so efficacious.

Pellagra in the Province of Rome.
